If the nerve has been completely divided the blood clot at the site of injury is rapidly transformed into scar tissue and the outgoing streams of axoplasm are almost all prevented from reaching the peripheral stump. They wander about in an aimless fashion, some penetrating the scar to some extent while others find their way laterally, and a few double back and twist round the central fibres. This great activity, together with the cellular proliferation that occurs at the end of the central stump, gives rise to the well-known central swelling which is called a neuroma. Effective regeneration cannot occur until the whole of the damaged segment has been excised and undamaged surfaces of the central and peripheral stumps brought into contact by accurate suture. When this has been done the Schwann cells of the peripheral stump, which multiply very considerably after division of the fibres, grow towards the central stump in longitudinally orientated strands which provide a sort of palisade along which the outgoing streams of axoplasm are conducted to the empty Schwann tubes of the peripheral stump. The destinations of the outgrowing axonal streams are entirely fortuitous. One from a central motor fibre may grow into a Schwann tube connected with a sensory end-organ. An axon formerly innervating one muscle may grow into a Schwann tube connected with another. Some of the small streams of axoplasm may wander down between the tubes and fail completely to make any sort of peripheral connexion. A point of particular interest is that when one of a number of streams flowing from a particular axon has grown down a Schwann tube and made connexion with an appropriate ending the other abortive outflows from the same axon gradually disappear. It appears that the successful axonal sprout is developed at the expense of its less fortunate fellows. Thus there is a progressive reduction in the number of streams of axoplasm growing from one axon.

In another type of injury, such as is produced by heavy pressure on a nerve, the axons and their myelin sheaths are interrupted without there being any break in the Schwann cells; this is the condition that has been termed axonotmesis. The process of regeneration is essentially the same, but since there is no break in the continuity of the Schwann sheath the growing streams of axoplasm are confined to their proper channel. They rapidly form into one stream which flows down along its proper course, reaches its appropriate end-organ, and rapidly increases in diameter. Hence, there is none of the constriction and wastage of axonal outgrowth such as must inevitably occur after division and suture of a nerve. This accounts for the striking difference in functional recovery after these two different types of nerve injury. Perfect restoration of function after suture can never occur, though in a purely motor or sensory nerve it is sometimes very good; on the other hand, after axonotmesis recovery will be perfect since the pattern of innervation is fully restored.

Myxoedema at the Menopause

Q.—Why should myxoedema appear at the menopause in healthy woman with no previous thyroid imbalance. Could an upper incisor tooth devitalized fifteen years ago be considered a causative or contributory factor?

*A.—*It is a known clinical fact that myxoedema may begin at a time of the climacteric. The cause of this is unknown, except so far as the climacteric is a period of endocrine adjustment, maladjustment, and involution of the gonads takes place; a similar way involution of the thyroid may take place, followed by fibrositis and hypothyroidism. It seems to the writer very improbable that the devitalized tooth can be a coincident factor. The treatment, of course, is thyroid extract.

Penicillin in Phenol Saline

Q.—I often use normal saline kept sterile by the admixture of 0.5% carbolic acid. Would this inactivate penicillin?

*A.—*Penicillin is not inactivated by phenol, parachlormetanesol, and other such substances used as preservatives. On the other hand, 0.5% phenol saline would be an undesirable vehicle for a solution to be injected repeatedly or in any considerable quantity.

Sexual Problems at Puberty

Q.—A worried parent has consulted me. His only son, aged 15, has begun to be interested in a girl of about his own age and has expressed a defiant determination to achieve sexual intercourse with her. I have said that the ideal of marriage must be inculcated and that the responsibility of explanation and example rests particularly with the father. The boy has very few friends, and has practised masturbation for about a year. What is the right approach to this kind of problem?

*A.—*One cannot answer this question adequately without knowing much more about the boy's personality and his background. But from the facts presented an explanation may be attempted. The age of 15 is a common one for the first romance, which, however, in the normal boy or girl is usually of a non-sexual type growing into a more sexual attachment about 17 or 18. This boy's sexuality is obviously of an exaggerated type, but excluding physiological overdevelopment this exaggeration is probably psychological. Masturbation is, of course, very common in boys of this age, and in itself is of little consequence. Excessive masturbation is most commonly resorted to as a solace for the feeling of lack of affection (there may not be a real lack); since no one loves him he will love himself. The lack of friends suggests such to be the case. In other boys masturbation is a reaction to a feeling of inferiority, since it gives a transitory feeling of well-being. In either case it is accompanied by defiance and a sense of grievance. Such a situation would explain his masturbation, his defiance, and his determination to gratify his passions at the onset of the heterosexual phase. Holding up marriage deals is sound; but moral injunctions are not likely to have much effect. The more deeply seated causes of this boy's reactions need to be investigated, preferably by a qualified child psychiatrist, or anyone who can win the boy's confidence. Its

roots probably go to much deeper resentments and a resort to sex in earlier childhood. Was there, for instance, any jealousy of another child? Did he feel neglected as a child, and did he resort to autoerotism as a solace? Has he a sense of grievance against either parent, and, if so, why?

Frequency of Micturition

Q.—Can anything be done to help a man aged 77 who complains of too frequent micturition? He has no symptoms of cystitis, no enlargement of the prostate, and no albumin or sugar in his urine.

*A.—*No mention is made in the question of a cystoscopy, and the existence of prostatic enlargement cannot be excluded by rectal examination alone. It is likely therefore that the patient is suffering from an intravesical projection of the prostate. If he is unwilling to undergo any form of operative treatment, or if for other reasons this is inadvisable, he should be fitted with a rubber urinal. By wearing this he will be able to attend meetings and social functions. The mere fact that he can pass water whenever he likes will relieve him of anxiety and reduce the frequency of micturition.

Formation of Red Cells

Q.—What factors are responsible for maintaining the red blood corpuscles at a relatively constant level in the blood? What changes occur in the life of the red cell as the individual ages?

*A.—*So far as is known the chief factor maintaining the red blood corpuscles at a relatively constant level in the blood is control of the rate of formation by varying oxygen tension in the bone marrow. A fall of the haemoglobin value below the normal level stimulates increased formation; when the value rises to normal the stimulus is reduced, and thus the value is kept fairly constant. If the value is increased above normal, as, for instance, by residence in high altitudes, on return to normal conditions there is probably no increased rate of destruction but the rate of formation is simply reduced below normal until normal conditions are once more attained. The life span of the red corpuscles does not vary with the age of the individual. In old age the decreasing amount of marrow simply leads to lower red cell counts than are found in younger individuals, but red cells produced probably survive for the same length of time.

Pethidine and Demerol

Q.—What is "demerol"? It is said to have the properties of morphine without the danger of addiction.

A.—"Demerol" is sold in this country under the name of pethidine. It is regularly advertised in the medical journals. Since it relieves pain it is not true to say that it has no danger of addiction. Addiction, however, is rare. Pethidine is 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, and from Jan. 1, 1947, it will come under the provisions of the Dangerous Drugs Acts.

Absence of Teeth

Q.—A small boy, aged 18 months, has not yet cut any teeth. A radiograph shows only one lower molar on each side, with no further evidence of any other teeth, upper or lower. The child is otherwise perfectly normal and healthy. Is any treatment needed? The mother of the child never had any lower incisors. She is pregnant again; are there any precautions she should take to try to prevent a similar condition in her next child?

*A.—*The absence of some or all teeth of the deciduous or permanent dentition, though not particularly common, is a condition that has been recorded on many occasions. Absence of teeth of the permanent dentition is on the whole more common than that of the deciduous. The most common teeth to be affected are the maxillary lateral incisors.

It is not clear from the question whether the lower molar shown radiologically is the permanent molar or deciduous molar. At 18 months approximately half the crown of the first permanent molar and the tips of the first and second incisors should be sufficiently calcified to be shown by x rays. If the permanent teeth are present, there is no reason for supposing that they will not erupt in the normal way. If the child

is healthy and there are no vitamin or hormone deficiencies there is no treatment indicated at present.

Absence of teeth is not infrequently hereditary. It is of interest in this particular case that the mother had no lower incisors. Unfortunately if the condition is hereditary there are no known precautions that can be taken to prevent a similar condition in the next child, though of course such absence may not necessarily be an inherited character with every child.

Cocaine Sensitivity

Q.—(1) Does cocaine sensitization exist or is it a myth? (2) Is it safe to use cocaine hydrochloride as a local anaesthetic injected into the tissues? (3) Is it safe to use a cocaine hydrochloride throat spray (say 10% as a preparation for laryngeal intubation) as a routine without first testing for susceptibility?

A.—(1) Cocaine sensitization exists in the sense that some people require very much less cocaine to acquire a certain degree of anaesthesia than others; it exists also in the sense that in some persons toxic symptoms arise after very small doses. Severe toxic effects have occurred after a dose as small as 20 mg. (1/3 gr.).

(2) It is not safe to use cocaine hydrochloride as a local anaesthetic injected into the tissues. Either procaine (B.P.) combined with adrenaline should be used for this purpose or, if a stronger anaesthetic is required, it is safer to use "nupercaine" (0.05–0.1% with adrenaline).

(3) There is no test for susceptibility which can be applied before using a throat spray; a 5% spray should be sufficiently strong for laryngeal intubation. It is wise to give the patient a barbiturate one hour previously (e.g., phenobarbitone B.P. 2 gr. or 0.13 g.) as this diminishes the risk of convulsions occurring. Patients with myasthenia gravis are specially susceptible to the risk of collapse due to cocaine or procaine.

Anencephaly

Q.—A patient has had one ovary and half the other ovary removed for cystic disease. After ten years of fruitless married life she produced an anencephalic monster. She is now pregnant again. What are the chances of a recurrence of this condition, and is abortion justifiable?

A.—A woman who has had an anencephalic child is more likely to produce another one than is the average woman. Nevertheless the absolute risk is not very great. The incidence of the condition rises as maternal age increases, but even should this patient be over forty the chance of the present baby being anencephalic is less than 1 in 20. It could be explained to her that the chances are heavily in favour of her child being perfectly formed. After all, the chances in any random pregnancy that the foetus will be malformed in one way or another are not so very different—say 1 in 50. In my opinion abortion on genetic grounds is quite unjustifiable. Anencephaly has been diagnosed radiologically at, of course, a relatively late stage. A radiologist might be consulted later as to whether examination was worth while; then, if the child did indeed prove to be anencephalic, the pregnancy might be terminated.

INCOME TAX

Professional Use of Residence

T. D. resides in a house separate from his surgery. All messages are received at his house, but patients are seen there by appointment only. The inspector of taxes declines to allow more than £10 in respect of the expenses of the house.

* In strictness T. D. seems to be entitled only to the amount of the additional expenditure (of all sorts) incurred in maintaining the house which is due to its use for professional purposes. Whether £10 is insufficient on that basis depends so much on the actual facts that it is not practicable to offer specific advice.

Training Grants for Demobilized Doctors

G. C. holds "a grade III post in the Government scheme for demobilized doctors while studying for the final F.R.C.S." Are the payments he receives taxable?

* We understand that such grants are regarded as subsistence allowances and are not liable to tax.

LETTERS, NOTES, ETC.

Swallowed Kirby Grips

Mr. A. M. DESMOND, F.R.C.S. (London, S.W.12) writes: In view of the recent correspondence (Sept. 7, p. 352) concerning the dangers of swallowed Kirby grips the following case may be of some interest. A female aged 4½ years was admitted to hospital on Aug. 15, 1946, the mother stating that the child had swallowed a Kirby grip six days previously. On the morning of admission she complained of lower abdominal pain. On examination the child was a little fretful, but otherwise did not appear ill. The tongue was clean, temperature normal, and pulse 128. There was lower abdominal tenderness but no guarding. Rectal examination revealed a tender lump centrally placed in the pelvis. The hair clip was not palpable; x rays showed the clip lying in the pelvis transversely. She was kept under observation, and in 24 hours the pain and tenderness had disappeared. On Aug. 17 x ray showed the clip in the same position. On rectal examination a "linear thickening" was felt, and this was thought to be the foreign body. Under general anaesthesia (ethyl chloride and ether) sigmoidoscopy was carried out, and the blunt end of the clip was seen just above the recto-sigmoid junction. Although grasped with forceps it would not be withdrawn. A finger was then inserted, and it was found that the clip had penetrated the bowel wall just above the recto-sigmoid junction and was buried to its hilt in a downward direction. By gentle manipulation it was found possible to invert and withdraw it. Pus was noted on the finger. Prophylactic penicillin and sulphathiazole were given for 24 hours, and the child made an uneventful recovery. This report again emphasizes the importance of treatment of these cases in hospital under skilled observation.

Digital Traction

Dr. S. J. NAVIN (Ombabika, Ontario) writes: In the *Journal* of Oct. 26 (p. 614) Dr. Kenneth M. MacLeod describes a "new" method for digital traction. I saw this method used by Dr. F. C. Barton, then a Flight-Lieutenant, R.C.A.F., in Gander, Newfoundland, in 1942 or 1943. Barton claimed no originality for his method, which I believe he got out of Scudder's textbook. At any rate this method of digital traction, which is very effective, is quite well known on this continent and has been in use for some time. In passing it may be noted that Barton used rubber bands tied to the piece of non-elastic suture material to secure his traction.

Haemospermia

Dr. SAMI KHAYATT (London, W.C.) writes: As regards the aetiology of haemospermia, discussed in "Any Questions" (Nov. 16, p. 758), I have to mention that in Tropical countries this condition may result from infection with *Schistosoma haematobium*. A few cases were reported in Iraq, and the diagnosis was confirmed by the finding of the terminal spined ova in the spermatic fluid. Probably these ova came from the capillaries of the seminal vesicle during ejaculation.

Car Sickness in Children

Dr. G. F. L. MITCHESON (Portslade) writes: In "Any Questions" (Nov. 30, p. 842) your reply makes no mention of the great value of hyoscine hydrobromide. I find in the case of my own children that a drink containing 1/200 gr. (0.32 mg.) of hyoscine hydrobromide given half an hour before a long car trip makes all the difference between joy and misery for us all.

Discovery of Chloroform as an Anaesthetic

Dr. ROBERT ANDERSON (Birmingham) writes: In 1890 I visited an old lady in Fifeshire who told me that when she was a young woman she was very friendly with Sir James Simpson, and that when he was experimenting with chloroform he used to give it to the guests at his drawing-room parties as if it were a parlour game.

Wilson's Disease: A Correction

Dr. A. DOYNE BELL (London, W.) writes: Your expert who answered the question on Wilson's disease (Dec. 14, p. 929) is surely guilty of a *lapsus calami* when mentioning neonatal jaundice as "a symptom of haemorrhagic disease of the newborn..." He should have written "haemolytic disease of the newborn." Haemorrhagic disease of the newborn, associated with a prolonged prothrombin time and effectively reacting to the administration of vitamin K, is not accompanied by jaundice or, usually, by lesions of the central nervous system.

Correction

In the *Journal* of Dec. 21, at p. 956, in Table I, category 9, whole-time teacher, qualified 8–14 years, column headed Total: No, the figure 233 should read 33, and the total at the foot of the column should be 3,267 instead of 3,467.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 28 1946

THE ACT AND COUNSEL'S OPINION

Counsel's opinion has been taken by the British Medical Association on two problems arising from the passing of the National Health Service Act. It is as follows:

Service Under the Act

The National Health Service Act, 1946, does not impose any obligation upon a medical practitioner to provide general medical services or any other services thereunder. On the contrary, Section 34 confers the right upon any medical practitioner engaged in medical practice (otherwise than as a paid assistant), if he wishes to provide general medical services under the Act, to apply before the appointed day to be included in the list. Any such medical practitioner is perfectly free to decide for himself whether he will apply to be included in the list or not. It is clear, therefore, in my opinion, that there is no possible justification for the statement that any such medical practitioner who elects not to apply is breaking the law.

The position is precisely the same, in my view, if the majority or indeed all of such medical practitioners elect not to apply to be included in the list. Moreover, I cannot see any ground for the assertion that any such medical practitioners who elect not to apply to be included in the list or (if it be the case that the majority of such medical practitioners have so elected) that the profession is challenging the authority of the law as promulgated by Parliament. Any individual or individuals who exercise an option which Parliament has enacted that he or they may exercise do not in my view thereby challenge the authority of the law as promulgated by Parliament.

It seems to me that this assertion is really founded upon the fact that, if a large number of such medical practitioners decide not to apply to enter their names upon the list, it may not be possible to operate the scheme of a comprehensive health service effectively or at all. The argument appears to be that Parliament has by this Act established a comprehensive Health Service and, as this Service can only be operated provided the majority of the medical practitioners co-operate by electing to join the Service, their failure to co-operate is a challenge to the authority of Parliament. This argument is in my view untenable and completely ignores the express provisions of the Act which give to the medical practitioner the right to elect whether he will or will not join the Service.

It must have been obvious to the Minister and to Parliament that in order to carry out the scheme it was necessary either (1) to compel medical practitioners under the Bill to join the Service, or (2) to make such satisfactory arrangements with the profession as would ensure the voluntary co-operation of the profession or the bulk of its members. Parliament did not think fit to make service under the Act compulsory. If, therefore, through the failure of the Government to secure the voluntary co-operation of the profession, a number of medical practitioners sufficient to work the scheme does not elect to join the Service, there is no justification in my view for saying that the profession is challenging the law as promulgated by Parliament. This opinion does not apply to such medical practitioners (e.g., employed by a local authority) as are liable to transfer under Section 68. Parliament has established a regular Army, Navy, and Air Force for which men can volunteer to join if they please. Men who do not volunteer to join do not thereby break the law or challenge the authority of Parliament.

A further question (which is wholly separate and distinct from the preceding question) arises as to the position of the

B.M.A. having regard to its Memorandum of Association. One of the objects of the Association is to maintain the interests of the medical profession. It is, however, provided that the Association shall not support with its funds any object or endeavour to impose on or procure to be observed by its members or others any regulation, restriction, or condition which, if an object of the Association, would make it a trade union. The B.M.A. has invited every member of the profession (including its own members) to decide by plebiscite whether he or she desires the Negotiating Committee to enter into discussions with the Minister on the regulations authorized by the Act. The form issued for this purpose states (*inter alia*) that a negative vote by general practitioners and members of visiting hospital staffs implies an undertaking by them, if so advised by the Association, not to enter the new Service.

One of the statutory objects of a trade union is "the imposing of restrictive conditions on the conduct of any trade or business," and, if the B.M.A. acted in such a way as to make this object its principal object, such acts would be *ultra vires* its Memorandum of Association. However, in my opinion the action taken by the B.M.A. in connexion with the plebiscite does not contravene the provision to Clause 3 of the Memorandum of Association. The undertaking is given only by those who vote in the negative and will be implemented only if the B.M.A. so advises. Those who gave the affirmative answer are not asked to give any undertaking and are at liberty to decide whether they will enter the Service. A question of difficulty might, however, arise if the B.M.A. at some future date made or sought to make a regulation that *none* of its members should enter the Service. I gather, however, that such a step is not and never has been contemplated by the B.M.A.

Hospital Treatment of Private Patients

The medical practitioners who may be allowed by the Minister to treat their private patients at a hospital providing hospital and specialist services are medical practitioners serving on the staff of such a hospital. Section 5 (2), however, clearly contemplates that medical practitioners serving on the staff of such a hospital may fall into two categories—namely, (1) those serving in an honorary capacity, and (2) those serving in a paid capacity. If, therefore, a consultant in private practice (whether he now holds the appointment of honorary consultant to a hospital or not) is hereafter appointed under Section 12 of the Act to the staff of a hospital providing hospital and specialist services in an *honorary capacity*, he would in my view be eligible to treat his private patients at that hospital or any other such hospital. It is not necessary for him to enter the Service in any way other than by such appointment.

It remains to be seen whether consultants in private practice, who desire to serve upon such hospitals in an honorary capacity, will ever be given the opportunity of doing so, or, if they are appointed, whether they will be permitted to treat their private patients in such hospitals. Appointments to the staff of such hospitals are made from persons selected by the appropriate advisory appointments committee by the Regional Hospital Board in the case of hospitals other than teaching hospitals, and by the Board of Governors in the case of teaching hospitals. Such appointments are, however, subject to regulations and directions given by the Minister (Section 12). The remuneration and conditions of service of all such officers are, subject to regulations, to be determined by the Regional Hospital Board or the Board of Governors as the case may be (Section 14).

Moreover, Section 66 empowers the Minister to make regulations with respect to the qualifications, remuneration, and

conditions of service of such officers and provides that no officer to whom the regulations apply shall be employed otherwise than in accordance with regulations. Therefore the extent to which consultants who desire to serve on the staff of such hospitals in an honorary capacity will in fact be appointed will depend upon the policy of the Minister and the regulations made by him and/or upon the policy of the Regional Hospital Boards or Board of Governors as the case may be and/or upon the Advisory Appointment Committees. The Minister could, in my view, if he so desired, block the appointment of consultants who desired to serve on the staff of such hospitals in an honorary capacity.

Moreover, even if a consultant secures appointment to the staff of such a hospital in an honorary capacity, he is not entitled as of right to treat his private patients at that hospital or any other such hospital. Permission has to be obtained from the Minister, who has a complete discretion to grant or refuse it. Further, the provision of special accommodation for private patients in such hospitals depends upon the discretion of the Minister and can only be made by him if, having regard to his duty to provide hospital and specialist services, he is satisfied that it is reasonable so to do. Therefore, though in theory consultants in private practice are eligible for appointment to the staff of such hospitals in an honorary capacity and to treat their private patients at one or other of such hospitals, it may be found in practice that few, if any, are given the opportunity to do so.

MEMBERSHIP OF TRADE UNIONS

The following letter has been sent to all local authorities from the British Medical Association:

December 16, 1946.

Dear Sir,

Trade Union Membership

The Association has considered, with particular reference to medical officers in the local government service, the position arising from the repeal by the Trade Disputes and Trade Unions Act, 1946, of the Trade Disputes and Trade Unions Act, 1927, Section 6 of which made it illegal for any local or other public body to require as a condition of the employment of any person that he should or should not be a member of a trade union.

Some local authorities have passed resolutions imposing on their employees a requirement of membership of a trade union or other organization. In this connexion I am instructed to inform you that the British Medical Association, which represents the great majority of doctors and enjoys a membership of over 54,000 and is the negotiating body for the medical profession, recognized as such by the Ministry of Health and the associations of local authorities, is opposed on principle to practitioner being required to join any body, British Medical Association or other—this does not of course apply to membership of medical defence societies. The Association prefers that membership should be voluntary, the strength of the Association remaining an expression of the profession's confidence in its representative body.

I should be glad to hear from you on this matter with regard to appointments under your Authority.

Yours faithfully,

(Signed) CHARLES HILL,
Secretary.

To the Clerk of the Council or the Town Clerk.

HOSPITAL DOMESTICS IN SCOTLAND

A clearer differentiation of the domestic from the nursing staff is implied in recent recommendations issued by the Secretary of State for Scotland. Hospitals should institute training schemes for domestic workers and provide better opportunities for promotion to supervisory positions. The properly trained domestic worker would have a higher standing and responsibility than at present, and for the supervisory posts might take a course at one of the Scottish colleges of domestic science. Large hospitals would have a whole-time domestic supervisor. Hospital authorities are asked to re-examine their arrangements for domestic work in the light of these suggestions.

HEARD AT HEADQUARTERS

Parliamentary Elections

The Public Relations Committee of the Association devoted the greater part of its last meeting to the whole question of parliamentary representation. This has been a difficult problem for the Association for many years past, though there has been a Parliamentary Representation Committee in existence and some sort of fund. A General Election in the ordinary course is little more than three years ahead and may be precipitated earlier. Difficulties arise out of the nature of the case, for Members of the House of Commons are representatives of constituencies and not of professional or other interests. Moreover, nearly all of them have party affiliations. University representation seems the most likely field to cultivate, but even here the way is not easy. Of all the leaders of the Association the late Sir Henry Brackenbury was one of the most suitable for the parliamentary arena, but his attack on the English Combined Universities in 1937, in spite of the support of the doctors' vote, left him at the bottom of the poll. The whole question is now receiving very careful attention, and the Public Relations Committee includes some able men of affairs.

Another matter of importance under consideration is municipal candidatures. Municipal bodies will have an enhanced importance from the point of view of health services. Mr. Bevan himself said in the Committee stage of the Health Bill that "these professional people," by which he meant in this case doctors, should normally find their way on to local councils by the ordinary course of popular election, and for that reason he stood out against compelling elected bodies to appoint persons who had not taken the trouble to stand. He was impatient with the argument that the busy general practitioner had no time for municipal elections; if he had no time to stand, said Mr. Bevan, he obviously had no time to serve. It is reassuring that the Public Relations Committee is including municipal as well as parliamentary matters in its consideration.

The Chronic Sick

The special committee recently set up by the Council to consider the care and treatment of the elderly and infirm had its first meeting recently. It is a strong committee, including among its members the chairmen of three of the principal standing committees of the Association as well as other persons both inside and outside the Council who have had special experience in this field. One representative of the Institute of Almoners is a member, and one member of the Association of Non-teaching Voluntary Hospitals; and the committee has power to co-opt three other members if necessary to secure representation of particular experience. The committee came to its task well documented. The extracts from the Hospital Surveys, which have done a great deal to direct public attention to the problem of the chronic sick, were laid before it, together with Sir Ernest Rock Carling's recent letter in the *Times*. Another memorandum was by Dr. A. G. Anderson, himself a member of the committee, who is chairman of the Medical Committee of the Scottish Advisory Committee of the Nuffield Provincial Hospitals Trust, and yet another was a succinct statement of the problem by three other members of the committee—Dr. Marjory Warren, Dr. E. B. Brooke, and Mr. L. Z. Cosin.

The "Doctors' Dilemma"

Shaw's play, the title of which has come in handy for newspaper headlines, is now out of date, and indeed it was never anything but a caricature of the medical profession, for doctors never have talked to one another as they talk there. But in one respect Shaw, writing forty years ago, showed remarkable prevision. This advice, in the preface to his *Doctor's Dilemma*, was written at a time when the present Minister of Health was only a boy of nine: "Make up your mind how many doctors the community needs to keep it well. Do not register more or less than this number, and let registration constitute the doctor a Civil Servant with a dignified living wage paid out of public funds." Shaw was insistent on the dignity of the wage: "Nothing is more dangerous than a poor doctor; not even a poor employer or a poor landlord."

Correspondence

The "Closed Shop"

SIR,—The specious arguments of the advocates of the "closed shop" have all the marks of the totalitarian mind. Dr. P. W. Roe (Dec. 14, p. 159) speaks of the "recalcitrant minority," as Nero doubtless spoke of the Christians, and Hitler of the anti-Nazis. The pellucid honesty of those who want to force doctors into trade unions is, of course, demonstrated by their remarkable belief that those who agree with them are so right that, despite their small numbers, they do, in fact, form the majority. The "freedom" that Dr. Roe alleges must follow the joining of a trade union must, I imagine, resemble the liberty of the caged tiger, who may no longer hunt for his food but is, of course, free from the danger of being attacked by other wild beasts.

I presume that Dr. Roe has heard of the political levy (tactful though it is not to mention it when freedom through coercion is the theme). Does he suggest that this also is a method of "ensuring the liberty and true freedom of the ordinary trade unionist"? What, may I ask, is an extraordinary trade unionist? Is he one who, having muscled in on the racket good and early, hopes to become one of those T.U.C. bosses who forcefully ensure "freedom" of the ordinary trade unionist?—I am, etc.

London, W.1.

A. PINEY.

The Willesden Affair

SIR,—I have sent the following letter to the chairman of the Willesden Urban District Council:

Thank you for having made up my mind for me. A few weeks ago I was prepared to extend a guarded welcome to the National Health Service. Now I am 100% opposed to it, your Council's action having brought vividly to my mind the wartime slogan, "Your freedom is in danger. Defend it with all your might."

Other members of the profession may feel as I do, and possibly it would be a good idea if all of them would send a letter similar to the above, notifying the Secretary of the B.M.A. that they had taken this action.—I am, etc.,

Lannceston.

DONALD M. O'CONNOR.

Medical Unemployment and Public Appointments

SIR,—*"F. B. P."* (Dec. 7, p. 152) ignores the grave disadvantages from which ex-Service holders of the D.P.H. suffer as the result of the loss of many years' experience in the public health service when seeking public appointments. This loss is particularly serious as the majority have not had the opportunity of gaining a great deal of experience before enlistment.

When applying for a public health appointment the candidate has first to fill in an application form which, under a large number of different headings, invites him to describe his previous civilian public health experience. Little if any space is devoted to the question of experience in the Forces. Later, if he is lucky enough to be called for an interview, he finds himself asked many searching questions regarding his work under different Acts of Parliament and in the various activities of public health authorities. No inquiry is made as to what he did while in the Forces, and he is given the unmistakable impression that such experience is considered irrelevant—an impression confirmed by results.

It will thus be seen that unless allowance is made to the ex-Service candidate for a deficiency in experience of public health work arising from his prolonged absence from civilian life, he does not compete on anything like even terms with the man who has remained in the public health service throughout the war.—I am, etc.,

EX-SERVICE D.P.H.

Dangerous Drugs Act: Withdrawal of Authority

The Home Office announces that Dr. John Stuart Prentice (Shap, Westmorland) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

H.M. Forces Appointments

ROYAL NAVY

Temp. Surg. Lieut.-Cmdr. (R.N.V.R.) the Hon. A. G. Gathorne-Hardy has been transferred to the R.N. in the rank of Surg. Lieut.-Cmdr.

Acting Surg. Lieut.-Cmdr. G. A. S. Anthony to be Surg. Lieut.-Cmdr.

Temp. Surg. Lieuts. (R.N.V.R.) W. H. B. Ellis, B. Geoghegan, and F. A. Lennan have been transferred to the R.N. in the rank of Surg. Lieut.

ROYAL NAVAL VOLUNTEER RESERVE

Prob. Temp. Surg. Lieuts. H. J. Shaw and D. C. G. Bett to be Temp. Surg. Lieuts.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. G. B. Hadden has retired on retired pay and has been granted the honorary rank of Col.

Lieut.-Col. C. Wilson, having attained the age for retirement, is retained on the active list supernumerary.

Major (War Subs. Lieut.-Col.) J. T. Robinson, O.B.E., to be Lieut.-Col.

Major M. A. Rea, O.B.E., to be Lieut.-Col.

Major J. S. Ruddell has retired receiving a gratuity and has been granted the honorary rank of Lieut.-Col.

Major W. R. M. Drew, O.B.E., has been seconded under the Foreign Office.

Major W. M. E. Anderson, D.S.O., has resigned his commission.

War Subs. Major N. Bickford to be Major.

War Subs. Major C. H. George, M.C., has retired and has been granted the honorary rank of Major.

Capt. A. Bennett to be Major.

Short Service Commission.—Capt. P. E. R. B. Unwin has retired, having received a gratuity, and has been granted the honorary rank of Major.

Short Service Commission.—War Subs. Major D. G. C. Whyte, D.S.O., from R.A.M.C., Emergency Commission, to be Lieut., and to be Capt.

Short Service Commission.—War Subs. Majors N. Bickford and D. G. C. Whyte; D.S.O., and Capt. H. J. McCann, A. R. T. Lundie, R. G. Macfarlane, and H. M. Macfie, M.C., have been appointed to permanent commissions.

Short Service Commission.—War Subs. Capt. J. B. Headley-Blythe and S. A. H. Lesser from R.A.M.C., Emergency Commissions, to be Capt.

Short Service Commission.—War Subs. Capt. A. S. Beare, from R.A.M.C., Emergency Commission, and A. W. Merrick, from R.A.M.C., T.A., to be Lieuts. and to be Capt.

Specialist Short Service Commission.—War Subs. Capt. J. K. Sueden, from R.A.M.C., T.A., to be Capt.

Specialist Short Service Commission.—Lieut. L. Mackie, from R.A.M.C., Emergency Commission, to be Lieut.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

War Subs. Capt. C. S. Pitt has relinquished his commission on account of disability, and has been granted the honorary rank of Capt.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Senior Training Corps.—War Subs. Major R. P. Smyth, O.B.E., supernumerary for service with Queen's University, Belfast, Senior Training Corps (Medical Unit) in the rank of Lieut.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Majors H. L. W. Sixsmith, O.B.E., R. C. Cunningham, and J. C. Shee have relinquished their commissions on account of disability, and have been granted the honorary rank of Lieut.-Col.

War Subs. Majors N. U. Khan and D. B. Wilson have relinquished their commissions and have been granted the honorary rank of Lieut.-Col.

War Subs. Capt. W. C. Muir, L. Werbeloff, and D. J. A. MacLean have relinquished their commissions and have been granted the honorary rank of Major.

War Subs. Capt. J. C. A. Davies and D. H. Lewis have relinquished their commissions, and have been granted the honorary rank of Capt.

War Subs. Capt. G. H. T. Lloyd has relinquished his commission on account of disability, and has been granted the honorary rank of Capt.

War Subs. Capt. L. Banski has relinquished his commission.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Miss) L. D. Barnhouse has relinquished her commission and has been granted the honorary rank of Major.

War Subs. Capt. (Miss) D. Mook Sang has relinquished her commission and has been granted the honorary rank of Capt.

Lieut. (Miss) E. Nankivell has relinquished her commission and has been granted the honorary rank of Capt.

ROYAL AIR FORCE

Wing Cmdr. L. I. Hyder has retired.
Fl.-Lieut. P. J. O'Connor, O.B.E., to be War Subs. Squad.-Ldr.
Fl.-Lieut. (Temp. Squad.-Ldr.) C. G. G. MacKay has been transferred to the Reserve of Air Force Officers and called up for Air Force service.
J. B. Ross to be Squad.-Ldr. (Permanent).
H. O'B. Howat to be Squad.-Ldr.
To be Fl.-Lieuts. (Permanent): W. O. Davies and R. Maycock.

ROYAL AIR FORCE VOLUNTEER RESERVE

D. A. Sanford to be Squad.-Ldr. (Emergency).
Fl.-Lieut. (Temp. Squad.-Ldr.) L. O'N. Knox has resigned his commission retaining the rank of Squad.-Ldr.
Fl.-Lieut. J. R. Fountain has relinquished his commission on account of medical unfitness for Air Force service, retaining his rank.
To be Flying Officers (Emergency): M. A. Coleman, L. V. Martin, J. D. Nelson, J. P. Nowlan, K. I. Roberts, L. Silverstone, G. I. Tewfik, T. A. Wylie, P. O. Yates, and E. V. de C. Medill.

INDIAN MEDICAL SERVICE

Major-Gen. Sir J. B. Hance, K.C.I.E., O.B.E., K.H.P., has retired.
Lieut.-Col. J. M. Mitchell, O.B.E., has retired, and has been granted the honorary rank of Col.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: S. Caruana, M.B., G. M. Glass, M.B., Ch.B., Medical Officers, Sierra Leone; D. W. F. Charlton, M.R.C.S., L.R.C.P., R. G. Davies, M.B., B.S., Medical Officers, Kenya; A. R. Duff, M.B., Ch.B., I. W. J. McAdam, F.R.C.S., A. B. Raper, M.D., M.R.C.P., Medical Officers, Uganda; J. E. Furness, M.B., B.S., R. H. Strudwick, M.B., Ch.B., Medical Officers, Nigeria; E. Scott, M.B., Ch.B., Lady Medical Officer, Nigeria; J. P. Lane, F.R.C.S., C. G. F. Smartt, M.R.C.S., L.R.C.P., Medical Officers, Tanganyika; D. Scott, M.B., B.Ch., Medical Officer, Gold Coast; R. H. Isaacs, L.R.C.P. & S., Medical Officer, Malaya; S. H. Moore, M.B., B.Ch., D.T.M. & H., Medical Officer, Hong Kong; C. M. Joyner, M.B., Ch.B., District Medical Officer, Bahamas; E. Morrison, M.B., Ch.B., Specialist in Anaesthetics, Health Department, Trinidad; S. Stecher, M.R.C.S., L.R.C.P., Medical Officer, Grade C., Trinidad; L. G. Eddey, M.B., Ch.B., Deputy Director of Medical Services, British Guiana.

Association Notices

CONSULTANTS AND SPECIALISTS COMMITTEE

As a result of the recently held elections, the following have been appointed representatives of Regions 8 and 17 of the Consultants Roll upon the Consultants and Specialists Committee for the remainder of the session 1946-7:

Region 8: Mr. D. A. Abernethy, Oxford.

Region 17: Dr. F. M. B. Allen, Belfast.

Diary of Central Meetings

JANUARY

- 9 Thurs. Publishing Subcommittee, 11 a.m.
Journal Committee, 2 p.m.

Branch and Division Meetings to be Held

MID-ESSEX DIVISION.—At Chelmsford and Essex Hospital, Sunday, Jan. 5, 1947, 10 a.m. Dr. Bathurst Norman: Coronary Artery Disease.

Meetings of Branches and Divisions

TUNBRIDGE WELLS DIVISION

Speaking on Nov. 27 Dr. John Thwaites said that a grave responsibility rested upon every member of the medical profession at the present time. The National Health Service Bill was now an Act of Parliament. The most important part of any health service was the doctors who worked in it. A health service was first and last a human service dealing with human relationships. It would have been common sense if the Minister had sought the co-operation of the representatives of the medical profession in framing his health Bill.

The declared policy of the Socialist Party was that sooner or later there should be a whole-time salaried State medical service, and the fact that this was still its policy had been confirmed in public speeches by leading members of the Government. The only reason that it was to be in the future was that the present time was not ripe for it. The opposition of the profession to such a type of service had always been adamant. The Act did infringe against some of the strongest of our principles. No specialist could work without beds and special apparatus for diagnosis and treatment.

As the Minister was to own and control hospitals of all kinds it seemed certain that in a very short time there could be no independent specialists. It was clear, too, that if the basic salary increased the Treasury would have a very real say in the distribution of doctors and would have a marked influence on the work of the central medical practices committee whose job it would be to decide the number of doctors to be allowed to practise in any area. Why should the Treasury pay out more salaries than they thought necessary? The doctor with the small practice would either be redundant or be allocated a greater number of patients.

The Minister was convinced that it was immoral for doctors to sell the goodwill of their practices, and on these grounds alone he wished to abolish our right to do this. But once they had lost the right to their own practices they had lost the last shred of their independence.

Those who were opposed to them (doctors) on political grounds were not slow to try to influence public opinion against them by saying that they were defying the will of the people as expressed by an Act of Parliament. But the Act did not say that all doctors must join the Service. It was left perfectly free for doctors to decide for themselves whether or not they would choose to work in the new Service.

It must be clearly understood that they would not and could not under any circumstances go "on strike." The doctors would be there to attend the sick and would do so; the hospitals would not close their doors and the public health services would continue to function.

Medicine and health should be outside the political field. It was the Government, by introducing into the non-political field their own particular political ideology of nationalization, who had made this conflict appear political. Nationalization of the health service would be contrary to all that was best in medicine and the development of medical science, and it must be fought to the bitter end. The profession had given ample evidence of its wish to take its share in the planning of a comprehensive health service for the country, and of its desire to see such a service come into being. I had also made it clear that there were certain fundamental principles which it considered essential to the structure of any health service and that any Act which did not respect these principles would be unacceptable to the profession. They wished to see the freedom of their patients and themselves remain intact; they wished to be employed by their patients and be responsible to them and not to third employing party, the State.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Sections of Surgery and Radiology.—Wed., 8 p.m. Discussion: The treatment of carcinoma of the tongue. Openers: Sir Stanford Cade, Dr. J. Ralston Paterson, and Mr. W. R. Douglas.

Section of Neurology.—Thurs., 8 p.m. Hughlings Jackson Memorial Lecture by Prof. E. D. Adrian: General principle governing nervous activity.

Section of Anaesthetics.—Fri., 5.30 p.m. Discussion: Anaesthesia for abdomino-perineal operations. Openers: Drs. Ronald Jarman and Frankis Evans.

POSTGRADUATE NEWS

The Edinburgh Postgraduate Board for Medicine (University New Buildings, Edinburgh, 8) announces a series of open lectures on subjects of wide biological interest to be given on alternate Tuesdays at 5 p.m., from Jan. 14 to March 11, 1947, in the West Medical Lecture Theatre of Edinburgh Royal Infirmary. All graduates and students are invited to attend the lectures. Details will be published in the diary column of the *Supplement* for the appropriate weeks.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BURKITT.—On Dec. 13, 1946, to Violet, wife of Dr. Robin Burkitt, M.D. F.R.C.S.I., a son.

CLARKE.—On Dec. 1, 1946, at London Hospital, to Katherine, wife of Dr. Owen Clarke, a son—John Owen.

COOPER.—On Nov. 18, 1946, at Newcastle, to Frieda, wife of Capt. J. R. Cooper, R.A.M.C., Corby, 26, Pierremont Gardens, Darlington, a daughter—Jennifer Ann.

GREENHALGH.—On Dec. 7, 1946, to Christine, wife of Dr. Eric Greenhalgh, Bramhall, Cheshire, a son.

WADDINGTON.—On Dec. 5, 1946, to Ella, wife of J. K. B. Waddington, F.R.C.S.Ed., 253, Nantwich Road, Crewe, a second daughter.

MARRIAGE

WAUGH—SMITH.—On Dec. 11, 1946, at the Church of St. John the Evangelist, Princes Street, Edinburgh, by the Rev. S. Harvie Clark, P.O. Ian Grant Waugh, M.A., B.M., B.Ch., son of Mr and Mrs. W. Grant Waugh, of Sunderland, to Catherine Mary Goodsir (Berry), M.B., Ch.B., daughter of Professor and Mrs. A. Sydney Smith, of Edinburgh.

INDEX TO VOLUME II FOR 1946

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Goitre and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

A

Abdomen, acute: Silent perforation of gut wall (W. Houston), 160—Apparently acute abdomen in pulmonary tuberculosis, 403
 ABRAMSON, J. Johnston: Recent advances in anaesthesia, 667
 ABRAMSON, E. L.: Dietary survey of 500 Swedish families, 236
 Abscess, breast, treated with penicillin (M. E. Florey and others), 845 (O); annotation, 805
 —extradural: Staphylococcal abscess (Guy myelitis with acute extradural abscess (Guy Stubbins and R. P. Jepson), 29 (O)
 Abstracting service Dutch, in English (leading article), 334
 Abstracts of *World Medicine*, 128
 —Surgery, Obstetrics and Gynaecology, 128
 Académie de Chirurgie de Paris: Centenary celebrations, 660
 Accidents, road, and alcohol, 776
 Achondroplasia, 251
 Achromotrichia in tropical malnutrition (William Hughes), 85 (O); correspondence, 277
 Acid phosphatase, 435
 Acidosis, review of book on, 818
 Adam, Flying Officer William Caldwell, death of, 315
 ADAMS, A. Wilfrid: Two-grade medical service under the Act, 475
 —Dorothy Mann, obituary notice of, 105
 ADAMSON, W. J.: Laboratory aid in general practice, 638 (C. B.): Congenital malaria, 241
 ADDERLEY, disease successfully treated by a graft (Addison's disease and H. Gardner-Hill), 570 (O)
 (L. R. Broster and H. Gardner-Hill), 570 (O)
 Adenoma of islets of Langerhans (A. W. Dickie), 817
 Adolescence: The unstable adolescent girl (report of Committee on Psychiatry and the Law), 909
 leading article, 904
 Adrenal tumour, hypertensive retinitis in (annotation), 952
 Adrenaline: Intravenous, in asthma, 242—And asthma, 678
 Afghanistan, inoculation experiments against typhus in (Zuhdi Berke), 994 (O)
 Age limit in advertisements, 1007
 AGNEW, Leslie R. C.: "Cord round the neck," 668
 Agranulocytic anaemia, primary (I. M. Librach and R. G. Cronin), 897 (O); annotation, 905
 Agranulocytosis, thiouracil, penicillin in treatment of (A. J. Thomas), 899
 Agriculture: Reconstruction by Way of the Soil (G. T. Wrench), 654
 AHRENVELDT, R. H.: Legal and medical "in-sooty," 170
 Aird, Capt. William Service, death of, 519
 AITKEN, Robert: The Problem of *Lupus Vulgaris*, 331
 ALBERT, Fritz: Belgian surgeons' acknowledgment, 98
 Alcohol, road accidents and, 776
 Aldred-Brown, George Ronald Pym, obituary notice of, 247
 ALEXANDER, S. S.: Socialism and the pay-bed, 176
 Allan, Flying Officer Charles King, killed in a flying accident, 879
 ALLEN, Clifford: Protection against sexual offences, 136, 441

ALLERGY:
 "Benadryl," 162; annotation oo, 233
 Cocaine, 1012
 Desensitizing solutions, 352
 Meaning of, 521
 Ménière's disease and (annotation), 127
 Penicillin: Allergic response to, 137—Allergic reactions to (A. I. Suchneck), 938 (O)
 Review of book on, 696
 Tuberculous, and immunity, 318

ALLISON, R. D.: Case of clicking ears, 930
 ALLWORTHY, S. W.: Itchy patient, 318
 ALSTEAD, Stanley: Cough syrus, 965
 ALSTON, J. M.: Control of air-borne infection, 832
 —Clinical pathological experience of penicillin, 959
 Amenorrhoea. See Gynaecology
 Amiable autocrat (book review), 860
 ANNAL, E. K. Jaak (and C. D. DARLINGTON): *Chromosome Atlas of Cultivated Plants*, 374

Amoebiasis, 838 1005—to Italy (Graham W. Hayward), 457 (O); correspondence, 794—Diagnosis of intestinal amoebiasis, 569, 703
 Amphetamine for air travel, 720
 Amputation prostheses (book review), 738

ANAEMIA:
 Hypochromic, review of book oo, 201
 Leuco-erythroblastic, 679
 Pernicious: Peripheral nerves in (annotation), 269—Sore tongue in, 406—Case of refractory (D. M. Zausmer), 774
 Review of book on, 901
 Sickle-cell, observations on, 435

ANÆSTHESIA:
 Action, theories of (J. H. Burn and H. G. Epstein), 533 (O)
 Advances in (C. Langson Hewer), 531 (O); correspondence, 667, 753, 504
 Anaesthesia (Journal of the Association of Anaesthetists of Great Britain and Ireland), 685
 Anaesthetic or anaesthetic? 711, 838, 1007
 Anaesthetic or anaesthetic? 711, 838, 1007
 Apparatus: Improved closed circuit (E. F. Gleadow), 90—Simple drip-feed type (Ralph Bibbins), 161—History and development of (A. Charles King), 536 (O); correspondence, 667

Basal, definition of, 802
 Centenary celebrations: Reprint of leading article from *Provincial Medical and Surgical Journal* of March 10, 1847, 541—Exhibition at Wellcome Museum, 621—Celebration dinner, 704

Chloroform: Reprint of J. Y. Simpson's article, "Discovery of a new anaesthetic agent more efficient than sulphuric ether," 541; correspondence, 753, 1012
 Curare: Technique for use of *d*-tubocurarine chloride with balanced anaesthesia (T. Cecil Gray and John Halpin), 293 (O); correspondence, 625, 789

Dental, after coronary disease, 843, 921
 History: Before and after Mortoo: historical survey of anaesthesia (E. Ashworth Underwood), 525 (O)—John Snow: anaesthetist and epidemiologist (1813-58), 535—Centenary celebrations, 621

Inhalation first use of, in Britain, 621
 Medicine's greatest gift (leading article), 546
 Pentothal: Drug eruption due to sodium pentothal (G. A. Grant Peterkin), 52; correspondence, 138, 172, 209, 340
 Perineal tear, local anaesthesia for, 479
 Review of books on, 16, 53, 495, 545

Through the eyes of a poet, W. E. Henley (Gunilla Liddle), 539 (O)
 Transfusion reaction inhibited, 964
 Trichlorethylene, apparatus for, in midwifery, 722

Trilene: Short survey of, in general practice (A. Barratt and S. H. B. Platts), 10 (O), 340; correction, 76; correspondence, 172, 210, 406
 —In midwifery, 514
 Vineshene, for repair of hare-lip and cleft palate (Phyllis F. L. Daplyn), 117 (O)

Analgesia. Lingual-nerve block for caeculi in Wharton's duct (I. Alan Carr), 228—Spinal analgesia in infant 11 days old (M. H. Armstrong-Davison), 264
 Anatomy, review of books, on, 160, 161, 373, 422, 494, 545, 616

ANDERSON, C. (and others): Royal College of Physicians of London, 476
 —H. G.: Flying Visit, 161—(And others): Reprints for medical missionary work, 669
 —John H.: Postgraduate education, 792
 —Robert: Discovery of chloroform as an anaesthetic, 1012
 —Lieut.-Col. William Maurice, obituary notice of, 143

ANDRESEN, Dr.: Refugees in Sweden, 660
 ANDREWS, C. H.: Spread of influenza, 61
 Anencephaly, 1012
 Aneurysm, intracranial, carotid ligation of, 502
 —of superficial temporal artery, 974
 —traumatic, Matas operation for (annotation), 20
 Angina pectoris, vitamin E in, 759
 —primary agranulocytic (I. M. Librach and R. G. Cronin), 897 (O); annotation, 905
 Angioblastoma of breast complicating pregnancy (J. B. Eutickoop), 51 (O)

Annotations:

Otitis media, penicillin for, 599
Pancreatitis, chronic, 75
Pantothenic acid, 843
Parasites, intestinal, in dogs and children, 843
Penicillin: Prophylaxis of streptococcal sore throat, 38—Booklet on therapy, 38—In pyorrhea, 147—Varicose ulcers and, 252, 352, 480, 722—Sterilization with, 407—Lozenges, effects of, 447, 448, 600, 638, 760, 884—For chronic otitis media, 599—For latent syphilis, 720—And normal saprophytes, 883—Massive dosage, 842—In osteomyelitis, 883—Toxicity of penicillin solutions, 973—In phenol saline, 1011
Pethidine: As drug of addiction, 448—And demerol, 1011
Phlebitis, treatment of, 251, 318
Phytic acid and osteoarthritis, 75
Pituitary extract: In obesity, 679—Use and abuse of, 803
Plastic bib, lethal, 804
Pneumoperitoneum, artificial, 148
Pneumothorax and air travel, 563
Polycythemia, treatment of, 758
Pregnancy: Prostin test for, 521—Air-travel and, 599
Pregnant syphilitic, 317
Prematurity and immaturity, prognosis in, 351
Protein digest material, 351
—hydrolysates, 36—For peptic ulcer, 184
Psoriasis, cause of, 110
Purpura in the elderly, 406
Rash after penicillin lozenges, 448
Renal glycosuria, significance of, 215
Respiratory infections, chemoprophylaxis of, 759
—murmur, 284
Rheumatic diseases: Literature on, 638—Chemo-prophylaxis of, 973
Rhinitis, chronic, treatment of, 38
Rowlandson print, 523
Sanatorium, a possible, 184
Schick test and pseudo-reactions, 75, 759
Scorpion sting, 680
Sex-determination, 216, 722
Sexual problems at puberty, 1011
Silliosis and bronchitis in saw-doctors, 599
"Silver ring," 599
Sinusitis, chronic, treatment of, 447
Smallpox, tests for, 148
Specks before the eyes, 284
Spermatozoa, counting, 97
Stammering in young child, 447
Stenosis, congenital pyloric, 407
Sterility in women, treatment of, 76, 110
Sulphonamide activity, effect of pus on, 843
Sunstroke and heatstroke, 252
Swallowed Kirby grips, 352
Sweets, effect of, on teeth, 184, 286
Syphilis: Criteria of cure, 285—Marriage and, 521—Secondary and latent, 522
T.A.B.: Inoculation of infants, 599—Reinoculation with, 803—In children, 882
Tattoo marks, removal of, 251
Teeth, absence of, 1011
Testicles, undescended, 636
Tetanus: Bite by dog with, 317—Risk of, in factories, 720—Treatment of, 843
Tetany, acid treatment of, 216
Threadworms in infants, 973
Thrombosis, coronary, and high altitudes, 318
Tobacco habit, 284, 523—Pipe v. cigarette, 523—Psychology of smoking, 638
Tongue-tie, treatment of, 521
Toxaemia, severe pre-eclamptic, with separation of retina, 599
Toys, soft, aseptic, 637
Travel: Sickness, 109—Rail travel for the sick, 804—Car sickness in children, 842, 930, 1012
Trichlorethylene in midwifery, apparatus for, 722
Trichomonas vaginalis and streptococci, 678
Triline administration, 406
Tuberculosis: Bone and joint, in children, 37—Heliotherapy in pulmonary tuberculosis, 598—Buffalo's milk and, 802—Bovine, 974
Twins, quick, 74
Urobilinogen excretion in infective hepatitis, 215
Vaccination, unsuccessful, 406
Varicose ulcers, 183—And penicillin, 252, 352, 480, 722
—veins, 680, 844—And menstruation, 721
Vitamin E: In heart disease, 562—In angina pectoris, 759
Vulvo-vaginitis, gonococcal, 146
Warts, plantar, 758
Whooping-cough (pertussis): Vaccine, 721—High flying for, 758
Wilson's disease, 929, 1012—And Rb incompatibility, 758
Woolner's tip, 252
Workmen's Compensation Act, 522

Notes, Letters, Answers, etc. (continued):

- Undulant fever. *See* Fevers
- Unesco and medical congresses (annotation), 378
- UNGAR, J.: Pertussis prophylaxis and control, 98—
(And R. DENSTON): Penicillin solutions for injection, 310—(Aod Arnold Soskov): Pure penicillin in ophthalmology, 723 (O); leading article, 740
- Ung. ichthyol, action of, upon inflammation, 562, 804, 884
- United States of America: Fellowships approved by National Foundation for Infantile Paralysis, 74—New York advancing (book review), 200—Army Institute of Pathology (annotation), 304—Post-graduate study for doctors, 345—Provision for hospitals under Hospital Survey and Construction Act, 694—Cancer control (annotation), 780—Venereal disease control (R. R. Willcox), 825 (O); correspondence, 920
- Universities and outside committees, 590
- University degrees, 388
- Birmingham: Degrees conferred, 105—Scholarships and prizes awarded, 105—Appointments, 181—Cambridge: Honorary degrees conferred, 29—Marmaduke Sheild Scholarship awarded, 29—Pass lists, 29, 72—Appointments, 72, 315, 1008—Degrees conferred, 72, 282, 596, 669, 799, 879, 923—Sir Comyns Berkeley bequest, 181—E. G. Fearnside Scholarship, 282—Election of Fellows, 558, 596, 879—Congregation, 596, 923—Research on relation of radiation to chemotherapy, 669—Post-graduate medical school, 923
- Dublin: Degrees conferred, 106, 248, 970
- Durham: Luccock Medical Research Fellowships established, 106
- Edinburgh: Honorary degrees conferred, 72—Appointments, 143, 282, 879—Resignations, 143—Degrees conferred, 181, 1008—Polish school, 181—1008—Scholarships and prizes, 181—Diplomas conferred, 717
- Glasgow: Degrees conferred, 106—Appointments, 182, 404, 444—Chancellor elected, 879—Leeds: Pass lists, 143, 558—Appointments, 839, 879—Emeritus professors, 839
- Liverpool: Pass lists, 72
- London: Appointments, 212, 248, 282, 404, 596, 717, 799, 839—Pass lists, 181, 248, 404, 669, 839, 923—Retirements, 212—Teachers recognized, 282—Bequest, 282—Scholarships awarded, 282—Professorship of Morbid Anatomy, 799
- McGill: Honorary degrees conferred, 598
- Manchester: Pass lists, 72, 143—Appointments, 212, 879
- Manitoba: Medical journals wanted, 600
- Oslo: Reorganization of medical curriculum, 924
- Oxford: Degrees conferred, 29, 72, 105, 248, 923—Honorary degrees conferred, 72—Theodore Williams Scholarship, 315
- Princeton: Honorary degrees conferred, 676
- Queen's, of Belfast: Price Lecture (evolution of clinical medicine as illustrated by the history of epilepsy) delivered by Gordon Holmes, 1 (O); correspondence, 176—Pass lists, 106
- Royal, of Malta (M.D.U. Malta): Reciprocity, 720
- St. Andrews: Pass lists, 72—Appointments, 558
- Sheffield: Appointments, 143, 282, 630, 799, 1008—Resignations, 143—Pass lists, 558—New Department of Child Health, 630
- Wales: Pass lists, 248, 970
- U.N.R.R.A., activities of, 271
- Uraemia, brain in (annotation), 127
- Urethra: giant urethral calculus in the female (Norman C. Lake) 328 (O); correspondence, 564, 590
- Urethritis, abacterial pyuria presenting as (A. B. Fieldsend), 493 (O); correspondence, 625, 837
- Urine, formates in, 252
- Urobilinogen: excretion in infective hepatitis, 215, 804
- Urology: Urological reflections, (Sir Henry Wade), 133—Problems of renal lithiasis (R. H. O. B. Robinson), 1000
- UROUHAUT, G. H.: Health Service Bill, 26, 307
- Urucaria, use of "benadryl" for penicillin (R. R. Willcox), 742 (O); correspondence, 875
- U.S.S.R., public health in (book notes), 422
- Vaccinia, generalized, 965
- VATZKY, J. Michael: Noma treated with penicillin, 14
- Vakil, C. B., obituary notice of, 754
- Van Someren, late Dr. E. H., 407
- G. A.: The plebsicite, 873
- R. K. A. (and others): Conus medullaris syndrome in spinal confusion, 87 (O)
- VANN, Douglas: Health Service Bill, 515
- VAROS-ZALAZAR, Roberto (and Waldemar E. Coutts): Abacterial pyuria with special reference to infection by spirochaetes, 982 (O)
- Varicella: Aod herpes zoster, 38; annotation, 426; correspondence, 564, 760—Chicken-pox eruption treated with benzyl benzoate (J. H. Beilby), 775—herpeticiformis, 138
- Varicose ulcers. *See* Ulcers
- veins: Retractor for surgery (R. Rowden Footie) 124—Statistics, 680, 844—And menstruation, 720
- VARTAN, C. K. Vesical calculus complicating proctodentia, 265
- Vascular injuries, observations on, with special reference to value of sympathectomy in ligation of main vessels (A. M. Boyd), 895 (O)
- VAUGHAN, Janet (and others): Incidence, incubation period, and symptomatology of homologous serum jaundice, 409 (O); leading article, 423; correspondence, 551
- Veins, deep, of calf: Modification of Ochsner and Mahorner test for patency (J. Rashleigh Belcher), 988
- VENEREAL DISEASES:
- Chancre, syphilitic, delayed appearance of, after penicillin (A. W. Frankland), 159
- Control: some American ideas (R. R. Willcox), 825 (O); correspondence, 920
- Gonococci, container for culture of, in carbon dioxide (John A. Burgess), 463
- Gonorrhoea: Gonococcal vulvo-vaginitis, 146—Problems arising from use of penicillin in (R. C. L. Batchelor and others), 151 (O)—Experimental (annotation), 549
- Notification, 64, 175, 313, 441
- Parasyphilis: Africans, peptic ulcers, and, 311, 514—Nomenclature, 711
- Penicillin, 175, 311
- Prevention, 441
- Review of books on, 53, 300, 737, 901
- Syphilis: Criteria of cure, 285—Case of secondary syphilis, iridocyclitis (R. J. Buxton), 299—Masked by penicillin, 311—Penicillin for pregnant syphilis, 317—Marriage and, 521—Secondary and latent syphilis, 522—Penicillin for latent syphilis, 720—Two unusual clinical manifestations of primary phase (P. D. Gordon Pugh), 945
- Trichomonas vaginalis* and streptococci, 678
- Venospasm, traumatic axillary (Hugh MacCarthy), 298
- VENTERS, Margaret: Erythroblastosis foetalis, 84 (O)
- VICKERS, B. Randall: Health Service Bill, 439
- Viret, Wilfrid F., obituary notice of, 798
- VISICK, A. Hedley: Conservative treatment of acute perforated peptic ulcer, 941 (O); annotation, 950
- Vision. *See* Ophthalmology
- Vital statistics in Western Europe, 833
- Vitamin: Is thiamine the antineuritic factor? 589—In human milk, 908
- B. neuropathy and deficiencies of (book review), 421
- C. nutrition in North-East England (James Black), 122 (O)
- deficiency after oral penicillin, 920
- E: In heart disease, 562—In angina pectoris, 759
- Vivian, Margaret: Varicose ulcers and penicillin, 252—Principle 2 and the health service, 401—Pronunciation of medical words, 516, 884
- Vivisection: Inspectors for experiments on animals, 180
- W
- WADDELL, H. M. R.: Health Service Bill, 340
- WADDINGTON, Peter: Health Service Bill, 307, 515
- WADE, Sir Henry: Urological reflections, 133
- WAGLAND, Wilfrid: Notification of venereal disease, 313
- WAKELEY, Cecil P. G.: Entertaining allowance, Royal Navy, 346
- WALKER, Kenneth: *I Talk of Dreams. An Experiment in Autobiography*, 901

SPECIAL PLATE

Federal Experiences to Japanese Captivity (E. E. Dunlop) facing 484 and 485

ILLUSTRATIONS IN THE TEXT

ADDISON'S Disease, Case of, Successfully Treated by Graft (L. R. Broster and H. Gardiner-Hill) .. 570
 Anaesthesia, Balanced, Technique for Use of *d*-Tubocurarine Chloride with (T. Cecil Gray and John Halton) .. 293
 — Before and After Mortuo: Historical Survey (E. Ashworth Underwood) .. 525
 — Vineshene, for Repair of Hare-lip and Cleft Palate (Phyllis F. L. Daplyn) .. 117
 Anaesthetic Apparatus, Improved Closed Circuit (E. F. Gleadow) .. 90
 — History and Development of (A. Charles King) .. 536
 — Simple Drip-feed Type of (Ralph Bibbings) .. 161
 Angioplasty of Breast Complicating Pregnancy (I. B. Enticknap) .. 51
 Aviation Medicine, Progress of, in R.A.F. and its Application to Problems of Civil Aviation (Sir Harold E. Whittingham) .. 39
 Barrier Creams, Evaluation of (C. G. A. Sadler and R. H. Marriott) .. 769
 Breast Abscesses, Treatment of, with Penicillin (M. E. Florey and others) .. 845
 — Milk Bank in Maternity Units (Martha Dynski-Klein) .. 258
 Burgerspital of Basle: Landmark in Municipal Hospital Building .. 500
 Calculus, Giant Urethral, in Female (Norman C. Lake) .. 329
 Carcinoma of Bladder Associated with Presence of Stone (James McNaughton Inglis) .. 13
 Cervical Mucus, Receptivity of, to Spermatozoa (Mary Barton and B. P. Wiesner) .. 606
 Chip Grafts in Neck of Femur (F. P. Fitzgerald) .. 861
 Conus Medullaris Syndrome in Spinal Contusion (G. A. Ransome and others) .. 87
 Crash Helmets (Sir Hugh Cairns) .. 322
 Digital Tracuton, Novel Method of (Kenneth M. MacLeod) .. 614
 Edwards, Arthur Tudor .. 346
 E.M.S. Huts, Adaptation of, for Children's Wards (Wilfrid F. Gaisford and E. H. Elkins) .. 867
 Enteritis, Acute, in Subtropical Climates (Ian Macgregor) .. 225
 Feeding, Inadequate, in Hospitals: Study of Contributory Factors (J. A. F. Stevenson and others) .. 45
 Fenestration Operation for Otitis (H. Macnaughton-Jones) .. 877
 Gonococci, Container for Culture of, in Carbon Dioxide (John A. Burgess) .. 463
 Gravity Drainage in Prone Position in Treatment of Digestive Fistulae of Abdominal Wall (David H. Patey and others) .. 815
 Haemoglobin and Protein Levels in Greece (Henry Foy and others) .. 486
 Haemostat and Needle-holder, Combined (J. S. Laurie) .. 654
 Hospital Boards, Regional, Areas of .. 1000
 Hydatidiform Mole, Case of, at Age 52 (A. H. Charles) .. 460
 Internal Combustion Engine and Spread of Disease (G. M. Findlay) .. 979

Intramuscular Injection, Sites for .. 147
 Irving Box: New Suggestion (H. Levon) .. 545
 Jaundice, Homologous Serum, Incidence, Incubation Period, and Symptomatology of (Naocy Spurling and others) .. 409
 Langdon-Brown, Sir Walter .. 556
 Laryngeal Foreign Body (Kennedy Hunter) .. 227
 Le Fleming, Sir E. Kaye .. 141
 Lovset's Manoeuvre for Breech Delivery .. 974
 Malignant Disease, Individual Resistance to (Michael C. Oldfield) .. 153
 Medical Students, Selection of (D. H. Smyth) .. 357
 Meningitis Due to Penicillin-sensitive, Sulphonamide-insensitive *Plutonium* b Strain of *H. influenzae*: Recovery (Constance F. Drysdale and others) .. 223
 Micromastia, Unilateral, Associated with Abnormalities of Musculature of Chest Wall on Same Side (E. R. Banner) .. 420
 Migraine and Sympathetic Nervous Pathways (G. F. Rowbotham) .. 319
 Mysis, Case of, Due to Warble-fly Larvae (Arthur Smith and Desmond P. Greaves) .. 120
 Needle for Intramuscular Injections at Regular Intervals (I. Bierer) .. 819
 Nicotinamide Deficiency after Oral Administration of Penicillin (P. Ellinger and F. Mackenzie Shattock) .. 611
 Ophthalmology, Pure Penicillin in (Arnold Sorsby and Joseph Ungar) .. 723
 Osteoarthritis, Treatment of, by Lactic Acid Injection (R. Mawson) .. 691
 Osteomyelitis, Acute, of Lumbar Spine in an Adult (Harry Freeman) .. 610
 — Pyogenic, of Spine (Peter Martin) .. 688
 Penicillin in Treatment of Common External Eye Infections (Joseph Milton) .. 324
 — Inhaler, New (L. Capper) .. 422
 Physiological Rest, with Special Reference to Arthritis and Nerve Lesions and to Manufacture of Appliances (Norman Capener) .. 761
 Post-operative Activity and Resumption of Normal Movement: their Influence on Embolism and Thrombosis (Gibson FitzGibbon) .. 413
 Retractor for Varicose Vein Surgery (R. Rowden Foote) .. 124
 Rupture, Transverse, of External Auditory Meatus (Douglas R. K. Reid) .. 859
 Sprue Syndrome, Onset and Cycle Development of (K. D. Keele) .. 111
 Thermometer, Skin, Resistance Type (W. A. Bourne) .. 332
 2-Thiouracil in Treatment of Congestive Heart Failure (E. P. Sbarpey-Schafer) .. 888
 Tip-up Hospital Trolley (C. E. D. H. Goodhart) .. 776
 Tobacco and Ulcer Dyspepsia (R. A. Jamieson and others) .. 287
 Tuberculosis, Chemotherapy of: Research in Past 100 Years (P. D'Arcy Hart) .. 805
 — in Industry (Frederick Head) .. 975
 Typhus: Experiences in Central Mediterranean Force (Herbert D. Chalke) .. 5
 Ulcer, Perforated Peptic, Aftermath of (William Houston) .. 221
 Venous Filling in Neck in Congestive Heart Failure, Aid to Measurement of (A. W. D. Leishman) .. 773
 Vulva, Oedema of, Due to Toxaemia of Pregnancy (J. P. Bush) .. 988
 Warfare, Chemical, Experiment Using Human Subjects (H. Cullumhine) .. 576

LONDON SATURDAY JULY 5 1947

AN INQUIRY INTO THE EPIDEMIOLOGY OF PEMPHIGUS NEONATORUM

BY

V. D. ALLISON, M.D., D.P.H.

AND

BETTY C. HOBBS, B.Sc., Ph.D., Dip.Bact.

(From the Emergency Public Health Laboratory, Institute of Preventive Medicine, Cardiff)

In recent years there has been a considerable increase in the incidence of pemphigus neonatorum, especially in nurseries in maternity hospitals and units. Cases and outbreaks have in the main been mild, with a very low mortality, but this does not lessen the administrative problems of isolation, quarantine, and ward closure. The rise in incidence of infection due to *Staph. pyogenes* not only in infants but also in nursing mothers, and bacteriological studies of infection in surgical operation wounds, war wounds, and industrial dermatitis, have led to an increased interest in the epidemiology of staphylococcal infections in general. The study of the epidemiology of pemphigus neonatorum and of other staphylococcal infections is rendered difficult by the ubiquity of the causative organism, and it is obvious that the application of any method whereby strains of *Staph. pyogenes* can be differentiated into types must inevitably lead, as in the case of *Str. pyogenes*, *Str. pneumoniae*, the typhoid bacillus, and *Salmonella* organisms, to more accurate knowledge of the sources and paths of spread of infection.

The most generally accepted criterion of actual or potential pathogenicity of staphylococci at present is the ability to produce coagulase, and as staphylococci may be golden, yellow, off-white, or white we have applied the term *Staphylococcus pyogenes* to coagulase-positive strains regardless of pigment production. The first acceptable differentiation of *Staph. pyogenes* into types was described by Cowan (1939), using a slide-agglutination technique whereby most strains of *Staph. pyogenes* were found to fall into three types and an atypical group among which he tentatively recognized five subtypes (personal communication). Differentiation of the subtypes is often difficult, as they are not always clear-cut, and a considerable amount of cross-reaction may occur owing to the presence of common antigens. In 1940 Christie and Keogh, using the same technique, succeeded in differentiating nine types, including Cowan's original three; their observations were based on reactions with absorbed and unabsorbed sera, and the organisms were classified according to the presence of major and minor agglutinogens, but they did not find it possible to eliminate the considerable antigenic overlap between different strains. A further development occurred in 1945, when Wilson and Atkinson described a method of differentiating types among *Staph. pyogenes* by means of bacteriophage action, evolved from the original observations of R. T. Fisk (1942) and

R. T. Fisk and Mordvin (1944); by this method they were able to recognize 21 types or subtypes and to apply the technique successfully to the investigation of several outbreaks of staphylococcal infection, in particular food-poisoning due to staphylococcal enterotoxin.

In the course of investigations to confirm and extend the work of Cowan and of Christie and Keogh, and to explore the possibility of obtaining more clear-cut results by agglutination methods, we were called upon to investigate outbreaks of staphylococcal infection causing pemphigus neonatorum and breast abscess in nursing mothers (Hobbs, 1944), food-poisoning due to staphylococcal enterotoxin (Murphy and Edward, 1944), and cases of sycosis barbae (Hobbs, Carruthers, and Gough, 1947). This provided an opportunity for testing experimental sera and for carrying out investigations on the epidemiology of staphylococcal infections, in particular pemphigus neonatorum.

In November, 1943, we were asked to investigate an outbreak of pemphigus neonatorum, affecting eight infants, in the main nursery of the maternity unit, City Lodge Hospital, Cardiff. This marked the beginning of a series of observations on the epidemiology of pemphigus neonatorum in the unit, which continued uninterruptedly for two years till November, 1945. During this period 2,719 infants were born in or admitted to the unit, of which 111 (4.1%) developed pemphigus neonatorum; all strains of *Staph. pyogenes* isolated from these patients were investigated serologically.

In addition, there occurred during the period of investigation 25 cases of staphylococcal conjunctivitis ("sticky eye"), either alone or associated with pemphigus neonatorum; cultures were taken from the infected conjunctivae for bacteriological and serological examination.

Procedure and Technique

(a) *Collection of Specimens.*—The specimens examined came from the lesions, nose, eyes, and occasionally umbilicus of infected infants, from the nose of healthy infants in infected nurseries, from likely sources of infection such as the nose, throat, and skin of infants' mothers, nursing, domestic, and medical staff, from air and dust in the nursery, and from infants' blankets and gowns. New patients were visited as early as possible in order to collect fluid from intact bullae by aseptic puncture with sterile Pasteur pipettes drawn out to a fine capillary. If the lesions were already open and discharging, swabs

were taken from the exudate after initial cleansing with sterile gauze. Nasal and eye swabs for infants were made from a fine pliable copper wire with a very small pyriform pledget of cotton-wool. Specimens for culture from skin were taken from the thumb, the terminal phalanges of the index and middle fingers, and the palmar and dorsal surfaces of the hand with swabs previously moistened with quarter-strength Ringer solution. Dust samples consisted of floor sweepings, which were collected in sterile test-tubes and shaken up in quarter-strength Ringer solution; cultures were made from tenfold dilutions. For air-sampling, blood-agar plates were exposed for one to three hours in the air of the ward during both quiet periods and periods of greatest activity. Blankets and infants' gowns were tested by soaking two small areas of about 12 sq. in. (75 sq. cm.) of each article in nutrient broth, cultures being made from the broth and from dilutions of the broth.

(b) *Laboratory Procedures.*—Agar plates containing 10% horse blood were the basic medium used for the culture and isolation of strains of *Staph. pyogenes*, but specimens from lesions were often cultured also on gentian violet (1/500,000) blood agar, especially if the presence of *Str. pyogenes* was suspected. Swabs still moist were inoculated direct on to blood-agar plates, but any which appeared to be dry were moistened with broth or quarter-strength Ringer solution. An ideal procedure was to incubate the swab in broth after inoculation of the plates. The broth culture after 18 hours' incubation was used for the tube-coagulase test (Gillespie, 1943), and if the direct plate showed no staphylococci the enrichment broth was plated out on to blood agar. By this method small numbers of staphylococci often missed by direct plating were isolated in almost pure culture. Following overnight incubation of the direct plate at 37° C. observations were made on the amount of growth, the types of organisms, and the proportion of colonies of *Staph. pyogenes*. From all cultures showing the presence of staphylococci at least two colonies were tested for their ability to produce coagulase by the slide-coagulase test introduced by Cadness-Graves *et al.* (1943), using human plasma. Pigmented strains which were coagulase-negative by the slide technique were re-tested by the tube method (A. Fisk, 1940). At least two coagulase-positive colonies from each culture were sub-cultured for serological typing. It was found advisable to leave the blood-agar plates on the bench for a few days to allow the full development of pigmentation and colony morphology. By so doing differences between types of colony became more obvious, and such differences were frequently found to correspond with different serological types, and often more than one type was present on a plate. Serological typing was carried out by means of the slide-agglutination technique described by Cowan (1939), using crude and absorbed sera from rabbits inoculated with vaccines prepared from Cowan's original three strains and from strains of additional types described by Christie and Keogh (1940). Agglutinating sera were also prepared against a number of freshly isolated strains which did not appear to fit into any of the hitherto identified types; these strains were cultured from various staphylococcal lesions during the course of the investigation. Many of the strains of *Staph. pyogenes* type Ib isolated from lesions during the second outbreak of pemphigus were typed by the bacteriophage method at the Public Health Laboratory, Oxford, and were regularly lysed by the same phage filtrates.

Prevalence of Pemphigus Neonatorum during the Period of Investigation

The maternity unit was housed in a 2-story block and consisted of a main nursery (Nursery 10) with 32 cots (later reduced to 16), a nursery for premature infants (10 cots), another 10-cot nursery, and five isolation nurseries (10 cots) together. In three of the six wards mothers and infants were nursed about 90 infants with their mothers, including isolation cases.

Prior to November, 1943, cases of pemphigus neonatorum in the unit had been rare, and had occurred singly and sporadically. Between November, 1943, and October, 1945, 132 cases of pemphigus neonatorum and staphylococcal

conjunctivitis occurred in the unit, and their distribution the various wards and nurseries is shown in Table I. It will be seen that 93 cases (70.5%) occurred in infant Nursery 10, attached to Wards 10 and 11, while 29 (22%) occurred in infants in Wards 8 and 9; there only two cases in premature infants. It is also to be

TABLE I.—Distribution of Cases

Totals:	107	21	4

that all 21 cases of staphylococcal conjunctivitis and that of the four cases of combined pemphigus and staphylococcal conjunctivitis occurred in Wards 8 and 9; Nursery 10. As over 70% of the cases were among infants in this nursery the epidemiological investigations carried out were centred round it.

The present investigation began when three cases of pemphigus occurring in Nursery 10 were reported to laboratory during the first week of November, 1943, at the unit was visited to take specimens for bacteriological examination. During the two succeeding weeks five further cases of pemphigus developed in this nursery, and serological methods of identifying the infecting strains of *Staph. pyogenes* had already proved successful in tracing the source of a small outbreak of pemphigus neonatorum in a private nursing home it was decided to widen the scope of the inquiry in order to discover the source of infection and the mode of spread.

Investigations and Results

Coagulase-positive staphylococci, usually in pure culture were isolated from the lesion of every case investigated including both pemphigus and "sticky eye." Swabs from the lesions of many cases were examined on repeated occasions, and in infants with multiple lesions sometimes several swabs were taken from different infected areas of the body. All the strains were subjected to serological examination and the infecting organism was typed in all but one of the 132 cases.

Distribution of Serological Types in the Lesions of Infected Infants

Fig. 1 shows the distribution month by month of the serological types of *Staph. pyogenes* isolated from all the cases in the maternity unit during the period of investigation. The total number of infants born in the maternity unit month by month during the period is also shown, and varied from 84 to 144, with a mean of 113.7. The number of cases of pemphigus and staphylococcal conjunctivitis per month varied from 0 to 22, with a mean of 5.5. In broad outline the chart shows a small sharp outbreak due to *Staph. pyogenes* type I which occurred early in November, 1943 (8 cases: 6 type I). This was followed by an outbreak due to type Ib which began in January, 1944, and continued with varying intermissions and recrudescences until May, 1945 (119 cases: 101 type Ib). Following an intermission of three months during which no cases occurred, there were indications of a third outbreak starting early in October, 1945 (5 cases: 4 type I), just as the investigation had to be terminated.

The first outbreak involved eight infants, all in Nursery 10, who were infected over a period of two weeks in November, 1943. *Staph. pyogenes* type I was isolated from the lesion of six infants; of the remaining two, one was infected with *Staph.*

pyogenes type I/II and the other with type IIIc. The latter infant was later reported to have been discharged from the unit with no evidence of pemphigus and to have been brought back one week later suffering from pemphigus and staphylococcal conjunctivitis. Type IIIc was also isolated from pus from the infected eyes and from the nose. During December no cases

FIG. 1.—The serological types of *Staph. pyogenes* causing pemphigus neonatorum and staphylococcal conjunctivitis among infants in a large maternity unit month by month from November, 1943, to October, 1945.

of pemphigus occurred, but in January, 1944, there were five cases, in two of which infection was due to *Staph. pyogenes* type I. From the three remaining cases *Staph. pyogenes* type Ib was isolated, and this type became the prevailing cause of pemphigus neonatorum in the unit during the remainder of the period of investigation. In February there were ten cases of pemphigus, all due to type Ib, and seven cases of staphylococcal conjunctivitis, of which four were caused by type Ib. During March no cases of pemphigus occurred in Nursery 10, but there were seven cases of staphylococcal conjunctivitis, of which four were due to type Ib, two to type I, and one to type Ia. A sharp rise in the incidence of pemphigus took place in May, mainly affecting Nursery 10 in which 21 cases occurred, 20 due to type Ib and one to type I. The one case of staphylococcal conjunctivitis in May was due to type IIIc. Following this outbreak in May, Nursery 10 was closed for a few days at the beginning of July and was thoroughly washed and cleansed. The nursery was reopened under less crowded conditions and there were no further cases of pemphigus in it in July, but six occurred during August and September, all due to type Ib. A further rise in incidence in this nursery took place between October and December, when type Ib caused 17 cases of pemphigus, one case of pemphigus and conjunctivitis, and two cases of conjunctivitis alone. The next five months produced nine cases, all due to type Ib, of which seven occurred in Nursery 10; but no more cases of staphylococcal conjunctivitis were observed up to the end of the investigation. There were no cases of pemphigus during June, July, and August, 1945, but in September there was one case due to type I. When the investigation was terminated in October there had been three more cases in Nursery 10 all due to type I.

Table II gives the numbers of cases of pemphigus and staphylococcal conjunctivitis which occurred throughout the investigation in the various nurseries and wards, and also shows the type distribution of the strains of *Staph. pyogenes* isolated from the lesions. It demonstrates, as already pointed out, that

P = Pemphigus neonatorum. C = Staphylococcal conjunctivitis.

type Ib, isolated from 102 (77.3%) of the 132 cases, was responsible for the great majority of the infections. It may also be noted that 73 (68.2%) of 107 cases of pemphigus and 17 out of 21 cases of staphylococcal conjunctivitis occurred in Nursery 10; between 50 and 60% of the infants born in the unit occupied Nursery 10.

Staphylococcal Conjunctivitis

A study of Table II shows that 87 (81.3%) out of 107 cases of pemphigus were caused by type Ib, and only 12 (57.1%) out of 21 cases of staphylococcal conjunctivitis were due to the same type; three out of four cases of combined pemphigus and conjunctivitis were due to type Ib. It would appear, therefore, that in an outbreak of pemphigus due to a particular serological type of *Staph. pyogenes* associated cases of conjunctivitis due to the epidemic type may occur, but there may also arise sporadic cases of conjunctivitis due to other serological types of *Staph. pyogenes* not prevalent as the cause of pemphigus, or indeed in the absence of pemphigus.

Swabs were taken from both eye and nose of nine cases of conjunctivitis, and seven showed the same type in eye and nose, the types being different in the remaining two. Swabs from four patients with coincident pemphigus and conjunctivitis yielded the same type from eye and lesion in each case, and in two cases from which nasal swabs were also taken the infecting type was found in the nose as well. When pemphigus and conjunctivitis occurred in the same patient, therefore, the double infection was caused by the same serological type of *Staph. pyogenes*. Also when conjunctivitis alone occurred the same type of *Staph. pyogenes* was present in the infected eyes and in the nose of a high proportion of cases.

Serological Types of *Staph. pyogenes* Isolated from Nursery Staff

Swabs were taken from the noses, hands, and occasionally the throats of the nursery, domestic, and medical staffs of the unit three times during the course of the investigation (Table III). The first of these occasions was in November, 1943, two days after starting the investigation of the first outbreak of pemphigus neonatorum in Nursery 10. Nose, throat, and hand swabs were taken from 15 members of the medical and nursing staff of the infants' nursery, and 10 (66.7%) were found to be harbouring *Staph. pyogenes* in one or more of the three sites. Four carried the epidemic type I, two harboured type IIIb, two type IIIc, and one each types Ia and Ib, all the nose. *Staph. pyogenes* was isolated from the hands of 9 members of the nursing staff, and all the strains belonged to the same serological types as were present in the infants' individuals.

The second swabbing of the staff took place in November, 1944, when cases in the second outbreak of type Ib were increasing in number. Of this outbreak was reached in May, hand swabs were taken from 40 persons, including sisters, nurses, pupil midwives, and was

was decided if not, the first of swabbings of the staff was a different light to the swab which was not

* One nurse (6.7%) harboured *Staph. pyogenes* type Ib in her nose. † Two nurses (5.0%) harboured *Staph. pyogenes* type I in the nose. ‡ Two nurses (4.2%) harboured *Staph. pyogenes* type Ib in the nose.

aff of wards and Nurseries 8, 9, 10, and 11. It appeared that most of the junior nursing staff had altered since the previous swabbing in November, 1943, as a regular change-over of pupil midwives took place every three months. Of 40 persons (72.5%) harboured *Staph. pyogenes*; 28 of these were nasal carriers and one had a positive throat culture only. The epidemic strain, type Ib, was harboured by 12 persons (30%), type Ia by six persons, types IIIa and IIIb by three persons each, type I (5%) by two persons, type IIIc by one person, while two persons carried unidentified types. Ten members of the staff had *Staph. pyogenes* in both nose and throat, and in eight the organisms in both sites were of the same type. Eleven persons showed *Staph. pyogenes* both in the nose and on the hands, and in nine instances the types were the same in both tests.

It was apparent that the percentage of the staff harbouring the first epidemic strain, type I, had declined from 26.7% to 5%, and that the second epidemic, type Ib, was now prevalent to a degree (30%) shown formerly by type I; in the first swabbing type Ib was found present in the nose of only one nurse (6.7%). These findings suggested that a high carrier rate among the staff of an infective strain of *Staph. pyogenes* would render the infant population of a nursery highly exposed to infection by that strain, and be followed by the appearance of initial cases of pemphigus neonatorum and of staphylococcal conjunctivitis. An opportunity to test this hypothesis was provided by the occurrence of a small number of cases of pemphigus due to *Staph. pyogenes* type I in September and October, 1945. Following three isolated cases caused by type Ib in March, April, and May there had been a lull in the incidence of pemphigus throughout the unit during June, July, and August. Alterations in the technique of routine procedures that may have been responsible for this decline in cases are described in a later section. At the beginning of October, 1945, nasal and hand swabs were taken from 48 members of the maternity staff, more than half of whom were pupil midwives who had recently joined the staff and had not been swabbed previously; 33 (68.8%) were found to be harbouring *Staph. pyogenes* in the nose and 10 on the hands. Eighteen of the nasal carriers carried type I, eight harboured type IIIb, three type I/II, two type Ib, and two type II. Again the most prevalent type present in the noses of the staff was that giving rise to the fresh cases of pemphigus in the nursery. Of the total staff 18 (37.5%) harboured type I, and only two individuals (4.2%) carried type Ib, which had been responsible for cases throughout 1944 and the early part of 1945 and which was present in the noses of 30% of the staff in February, 1944. The first two swabbings of the staff had been carried out during the height of outbreaks of pemphigus, and it was impossible to decide whether the high nasal carrier rate of the epidemic strain was a cause or a consequence of the outbreak. The third swabbing, however, was carried out after a case due to a different type had occurred, following a period of three months during which there had been no cases of pemphigus or staphylococcal conjunctivitis. The presence of a high proportion of

nasal carriers of the infecting type among the staff at this early stage strongly suggests that a build-up of nasal carriers of a potentially infective strain occurs among the staff before the appearance of cases of pemphigus.

Twelve members of the nursery staff were swabbed on two or more occasions. Nasal swabs from five either showed non-epidemic types of *Staph. pyogenes* or were negative. Of the remaining seven, four harboured the prevalent epidemic type once, while the remaining three yielded the prevalent epidemic type each time they were swabbed. The numbers are too small for any deductions to be drawn regarding the frequency of change of serological type of *Staph. pyogenes* in the nose in relation to the prevalent epidemic type.

Staph. pyogenes in Noses of Healthy Infants in the Infected Nursery

In addition to swabbing the staff, nasal swabs were taken from all the healthy infants in Nursery 10 on two occasions (Table III). First in November, 1943, at the time of the outbreak due to *Staph. pyogenes* type I, nasal swabs were taken from 32 healthy infants in the nursery; 28 (87.5%) were found to be harbouring *Staph. pyogenes* and 11 (34.4%) carried the epidemic type I and were free from clinical infection. Type Ia was isolated from six infants, type Ib from three infants, and type II from two infants, while 13 strains could not at that time be typed. Seven of the infants harboured more than one serological type of *Staph. pyogenes*. The infants harbouring type I were scattered throughout the nursery and there was no concentration of infants in neighbouring cots showing the same serological type in their noses.

When, in October, 1945, after a period of three months' freedom from infection, cases of pemphigus due to *Staph. pyogenes* type I began to appear in Nursery 10, nasal swabs were again taken from all of 18 infants in the nursery. Swabs from five of the infants, ranging in age from 5 hours to 2 days, failed to yield staphylococci; of the remaining 13 infants, aged from 4 days to 2 months, 11 (61.1%) were heavy carriers of *Staph. pyogenes*. The types were fairly evenly distributed, no single type being predominant, and the high nasal carrier rate of type I among the staff was not at this stage present among the infants.

Staph. pyogenes in the Nursery Air and Dust

Blood-agar plates were exposed in Nursery 10 on two occasions—first during the outbreak of pemphigus in November, 1943, and again in October, 1945. On the first occasion five plates were exposed at cot level in different parts of the nursery from 2 to 5 a.m. and a second series from 7 to 10 a.m., periods of least and greatest activity respectively in the nursery. A total of approximately 3,000 colonies, representing bacteria-containing particles, were counted on plates exposed from 2 to 5 a.m. Plates exposed from 7 to 10 a.m. were too overcrowded for counting. The organisms on the plates were predominantly saprophytic cocci and bacilli, but *Staph. pyogenes* was present in small numbers. Of three colonies of *Staph.*

Staph. pyogenes subcultured for examination two were identified as type I. The second exposure of plates in the nursery in October, 1945, yielded approximately 2,000 colonies during the early morning period and approximately 10,000 colonies during the active period between 7 and 10 a.m. Again *Staph. pyogenes* was present only in small numbers, but type I, which was at that time the cause of pemphigus, was identified on plates from four different sites.

It was evident, therefore, that the epidemic strain of *Staph. pyogenes* was present in the ward air during both periods of exposure, but it was not possible from these investigations to estimate to what degree, although it appeared to be low.

Two samples of dust from the floor of Nursery 10 were examined in November, 1943. The samples were collected into sterile jars from the routine morning sweepings. Cultures yielded large numbers of organisms, mainly saprophytic, but *Staph. pyogenes* was present in considerable numbers in one sample, while the other yielded scanty colonies. Of 18 colonies of *Staph. pyogenes* examined serologically five were identified as type I, four as type IIc, one as type Ib, while the remaining eight could not be typed. The epidemic type I therefore represented 28% of a random sampling of *Staph. pyogenes* in the floor dust of the nursery; the remaining identified strains belonged to types which were found in the noses of members of the nursery staff and of healthy infants in the nursery.

Staph. pyogenes in Infants' Blankets and Gowns

Staph. pyogenes was isolated from five out of six blankets from cots in Nursery 10 in November, 1943; type I was found on one blanket and types Ib, II, IIb, and IIc on the others. One blanket was re-examined after laundering, and *Staph. pyogenes* type I was isolated from nutrient broth in which part of the blanket had been soaked and also by shaking the blanket over exposed blood-agar plates. Two flannel gowns belonging to infants in Nursery 10 were examined after laundering; one gown yielded *Staph. pyogenes* type IIb and an untypable strain, while no staphylococci were isolated from the other.

Table III gives a summary of the results of examinations of ulcers from material taken in relation to the three outbreaks of pemphigus neonatorum in Nursery 10. It shows the regularity with which the epidemic types were found in the noses of a high percentage of the nursery staff, and elsewhere in the infants' environment, and suggests that widespread distribution of an infecting strain in the nursery environment may bear a causal relationship to the onset of an outbreak. Members of the staff swabbed during the second and third outbreaks included those engaged on nursing duties in other nurseries and wards of the unit, especially Ward and Nursery 8'9, in which 23 out of 24 cases of pemphigus and three out of four cases of staphylococcal conjunctivitis were caused by *Staph. pyogenes* type Ib.

Distribution of Infecting Types of *Staph. pyogenes* in Eye, Nose, and Umbilicus of Infected Infants

During the course of the investigation swabs were taken from 102 of the 111 cases of pemphigus neonatorum, not only from the lesions but also from other sites on the body, including the nose, eye, and umbilicus. Table IV shows the numbers of

TABLE IV.—Correlation Between Serological Types of *Staphylococcus pyogenes* Isolated from the Lesion, Eye, Nose, and Umbilicus of Cases of Pemphigus Neonatorum (Total Number of Cases Examined—102)

Sites	No. of Cases Examined	Same Serological Types		Different Serological Types	
		No.	%	No.	%
lesion and nose	102	75	73.5	27	26.5
lesion and eye	91	64	70.3	27	29.7

lesion, eye, and nose	91	55	60.4	36	39.6
lesion, eye, nose, and umbilicus	16	8	50.0	8	50.0

cases from which the various combinations of swabs were taken and the numbers and percentages of cases in which strains of

Staph. pyogenes were serologically identical or of different serological types. In general it was found that there was a remarkably high association between the serological types of *Staph. pyogenes* present in lesion and nose, lesion and eye, and lesion and umbilicus, with a lower but still notable association between the types when more than one site was swabbed in addition to the lesion. Findings, already quoted, indicated the ubiquity of the infecting strain in the infants' environment, and these figures show that the wide dispersal extends also to the infants' healthy skin, upper air-passages, and exposed mucous surfaces such as the conjunctivae.

Serological Types of *Staph. pyogenes* Isolated from Mothers of Infected Infants

Apart from the nursery staff, consisting of doctors, nurses, and ward-maids, the only persons with whom the infants came into contact were the mothers, during breast-feeding. It was therefore decided to investigate serologically the staphylococcal flora of a number of mothers as a potential and intimate source of infection.

Swabs from the nose, throat, and in a few cases samples of the breast milk were taken from mothers of infected infants to see what relationship, if any, the serological types of *Staph. pyogenes* isolated from the mother bore to the type isolated from the infant. Swabs from the infants were taken from the lesion and from some or all of the following sites—nose, eye, and umbilicus. Table V shows the results of the examination

* Septic finger occurring after infection in her infant.

† Small septic lesion on breast following infection in her infant.

of strains of *Staph. pyogenes* isolated from 15 infected infants and from their mothers. In only six instances—viz., Nos. 1, 3, 4, 10, 13, and 14—was the serological type of *Staph. pyogenes* causing the infection in the infant also isolated from the mother; five of the six mothers harboured the organism in the nose, and in one (Mrs. Co., No. 3) it was found only in the breast milk. In the case of Mrs. Jo. (No. 4) the organism was isolated from the nose, the throat, and from a septic finger which occurred after her infant became infected with pemphigus, so it seems likely that she was infected by her infant. A similar explanation may account for the septic lesion in the breast of Mrs. Pi. (No. 13). If these two are eliminated, or even if not, the correlation of infecting strains in mother and infant is low. These findings, taken in conjunction with the results of the bacteriological investigations in Nursery 10, lend weight to the view that infection was spread in the nursery and was not transmitted to the infants by their mothers.

Discussion

The results of the serological identification of strains of *Staph. pyogenes* isolated from the lesions of 132 cases of pemphigus neonatorum and staphylococcal conjunctivitis occurring in a large maternity unit over a period of two years show that there were three separate outbreaks, each due to a distinct serological type of *Staph. pyogenes*. The organisms causing the outbreaks were isolated not only from lesions but also from the eyes and noses of a large proportion of infected infants, from the noses of healthy infants in the same nursery, and from the noses of a large proportion of the staff. During one outbreak the epidemic type was also isolated from air, dust, bedclothes, and infants' gowns in the nursery. It was evident, therefore, that the epidemic types were widespread in the infants' environment, and the results of different surveys of staphylococcal types found showed that this high concentration of the epidemic type in the noses of the nursery staff was present not only at the height of an outbreak but also in the early stages of an epidemic.

It is accepted that the main reservoir of *Staph. pyogenes* is the upper respiratory tract of man, in particular the nasal passages; but the organisms may also be present on the skin of a considerable proportion of the population (Gillespie, Devenish, and Cowan, 1939; McFarlan, 1942), and higher carrier rates were found among hospital in-patients and nurses than among the general population (Miles, Williams, and Clayton-Cooper, 1944). In the present investigation 72 (70%) of 103 members of the staff swabbed on three different occasions were carrying *Staph. pyogenes* in the nose, and in 34 instances (33%) the strains isolated belonged to the epidemic type; 28 members of the staff who harboured *Staph. pyogenes* in the nose were also hand-carriers, and in 15 instances the strains cultured from the skin were identified as the epidemic type. No hand-carriers of *Staph. pyogenes* were found among the 31 members of the staff whose nasal swabs were also negative. There was therefore confirmation of the close association between nasal carriage and skin carriage of *Staph. pyogenes*. The high percentage of the staff found to be carrying the epidemic types was probably not an accidental congregation of persons harbouring those types, but more likely a gradual build-up of infection by a strain possessing the ability to implant itself and multiply in the nose when spread from person to person.

The possible sources of infection of the infant with *Staph. pyogenes* are those who come into contact with it, either directly or indirectly, and include mother, doctor, nurse, ward-maid, and laundress. The mother may infect her own infant during breast-feeding, but the evidence shows that the spread of infection takes place in the nursery. The contacts between doctor and infant after it has been born are in general irregular and transitory, and there is little or no evidence that he plays any part in the spread of infection. The same conclusion applies to the ward-maid, whose presence in the ward is of short duration with only indirect, if any, contact with the infants. The laundry is a potential source of infection, either through failure to rid blankets and infants' gowns and napkins of staphylococci or by infection during handling. The nurse is in regular and intimate contact with the infants, especially during toilet and hygiene, and the evidence suggests that she is the most important factor in the spread of infection. This evidence is based on the epidemiological, bacteriological, and serological findings, and as a result of visits to different maternity units and nursing homes in order to watch the procedure and technique of infant hygiene and nursing.

The possible paths of spread of infection are represented in Fig. 2, which shows infection spreading from the adult nose at the centre via hand, fomites, air, and dust to the infant's skin, nose, and eye at the periphery. In the present investigation *Staph. pyogenes* has been found to be so ubiquitous in the infants' environment that no precise conclusions could be drawn regarding the mode of spread. The serological types of *Staph. pyogenes* which were the cause of the outbreaks were isolated in cultures on repeated occasions from the sources shown in the diagram, although infection of dust and air appeared to be low. The most probable path is via the nose and hands of the midwife or nurse to the infant's skin, but the infant's communal bath and towel also probably play an important part in the transmission of infection.

FIG. 2.—Potential paths of spread of infection in nursery outbreaks of pemphigus neonatorum and conjunctivitis.

Knowledge of the possible paths of spread of infection alone will not suffice as a basis for the prevention or control of outbreaks of infection. Factors which facilitate the spread of infection must also be considered and steps taken to eliminate them. During visits to several maternity units and nursing homes in which outbreaks of pemphigus neonatorum had occurred, many such factors were noted. One of the chief among these was overcrowding and bad spacing of cradles or cots: in one large nursery capable of accommodating a maximum of 18, allowing a minimum of 25 sq. ft. (2.3 sq. metres) per cot, there were 32 infants. Insufficient ventilation and light, partly due to black-out conditions and the building of anti-blast walls, were also noted as undesirable factors. In most of the units visited the wards and nurseries were cleaned by dry dusting, a practice which was immediately altered when attention was drawn to it. Associated with the overcrowding of nurseries the nursing staff was often inadequate, and too much of the toilet and hygiene of the infants had of necessity to be carried out by pupil midwives insufficiently supervised and still in an early stage of training with little or no knowledge of the nature of infection and modes of transmission. Other points facilitating the transmission of infection noted in different hospitals were: the communal changing-table covered with a towel on which all infants were placed in turn; failure to disinfect the bath after use for each infant; failure to wash the hands before and after attending to an infant; toilet requisites handled by different nurses and used in common for all infants in the nursery. Masks were employed in all the maternity units and nursing homes visited, but in one large maternity unit masks were often worn covering the mouth only, leaving the nose exposed.

Until more precise knowledge is available of the paths by which staphylococcal infections are spread in nurseries, it is justifiable to recommend measures to prevent and control outbreaks covering a wider range than may later be found necessary. Benians (1943) showed that the mere closure of a ward in which an outbreak had occurred, followed by cleansing and airing, was ineffective in terminating an outbreak, as fresh cases began to appear within three days of reopening the ward. It has also been pointed out by Elliott, Gillespie, and Holland (1941) that the use of masks, gowns, and rubber gloves alone did not have any observable effect on the spread of infection. Most of the

factors already noted as facilitating the occurrence and spread of infection suggest the obvious remedies—avoidance of overcrowding, adequate ventilation and natural light, a proper proportion of trained and untrained nursing staff with more supervision of the latter, and early training in the nature, sources, paths of transmission, and methods of prevention and control of hospital infections.

The ward or nursery should be cleaned by vacuum cleaner or by damp dusting. The infant's bath should be thoroughly disinfected either with undiluted lysol (M.R.C., 1941) or with 1% C.T.A.B. (Barnes, 1942) and washed after use by each infant, and well rinsed before again being used. So far as practicable a separate toilet outfit should be reserved for each infant, including the towel on which it is placed after its bath, if different from that with which it is dried. Consideration should be given to the changing of infants in their cots instead of on a communal changing-table, as is the practice in many maternity units, while the crib bath in an individual bath blanket has much to recommend it.

No member of the nursery staff—medical, nursing, or cleaning—should go on duty or enter the nursery if suffering from any acute upper respiratory infection or skin sepsis. Efficient masks covering both mouth and nose should be worn by all staff when in the nursery. Masks should be changed frequently, as they may become moist, rendering them inefficient and unpleasant to wear. The nurse's hands should be washed in soap and water and dried either with destructible tissue towels, which are again on the market, or on her own towel immediately before and after attending to an infant, and especially after every use of the handkerchief. Hamburger and Green (1946) have pointed out the importance of nose-blowing in the expulsion of *Staph. pyogenes* by nasal carriers, with infection of the hands and transfer from hands to secondary environmental reservoirs, such as clothing, bedding, towels, etc. This may be an important factor in the infant nursery as a source and mode of spread of staphylococcal infection, in view of the high percentage of persons in a semi-closed community, such as a hospital, who harbour *Staph. pyogenes* in the nose.

Members of the nursery staff who are aware that they are heavy nasal or skin carriers of *Staph. pyogenes* should be most meticulous in observing preventive measures even in the absence of staphylococcal infection in the nursery. Attempts to clear profuse nasal carriers of *Staph. pyogenes* with sulphathiazole snuff or ointment have not had the hoped-for success, but the application of penicillin ointment to the nostrils two or three times daily and sniffed in, recommended by Hobbs, Carruthers, and Gough (1947) as an adjunct to the treatment of sycosis barbae, may be more effective.

The numerous administrative and technical procedures necessary to prevent and control the spread of infection among infants in large nurseries in maternity hospitals—procedures which in many instances are not possible or practicable—give rise to consideration of the question whether the large infant nursery should not eventually be discarded in favour of the mother and infant being nursed together in a cubicle or in small wards. Apart from the respiratory and intestinal infections to which the newborn infant is so highly susceptible, it would not be exposed to the high concentration of infection which develops in a nursery in the earliest stages of an outbreak of pemphigus neonatorum, and the number of contacts, direct and indirect, would be very considerably reduced. The primipara, moreover, would have more opportunity for guidance and practice in the feeding, toilet, and hygiene of her infant. In any event the prevention and control of infection should be based on high standards of nursing technique and infant

hygiene as exemplified in Medical Research Council War Memorandum No. 11 (1944).

Summary

An outbreak of pemphigus neonatorum and staphylococcal conjunctivitis affecting 132 infants in a large maternity unit over a period of two years is described.

Serological identification of strains of *Staph. pyogenes* isolated from the lesions of all the cases showed that there were three outbreaks, each due to a distinct serological type of the organism; there were also a small number of sporadic cases due to different serological types of *Staph. pyogenes*.

Investigations in one large nursery in which 93 of the cases occurred showed that the infecting strain was widespread in the infants' environment, and was isolated from the noses of a high proportion of the nursing staff, from the noses of healthy infants, from blankets and gowns, and from dust and air in the nursery.

The findings indicate that the infants were infected in the nursery and not from their mothers.

The evidence suggests that the main reservoir of infection was the nasal passages of the nursing staff, whence infection was spread to the infants, probably via the hands.

Recommendations are made for the prevention and control of staphylococcal infection in infant nurseries.

We gratefully acknowledge the facilities afforded to us for these investigations by Dr. John Jones, City Lodge Hospital, Cardiff, and the willing and valuable co-operation of Dr. Olwen Williams, Sisters Priday and Davies, and the staff of the maternity unit. We also obtained much valuable help and information from several other maternity units and private nursing homes.

There are now 12,000 industrial canteens known to the Chief Inspector of Factories, and more than half of these are in factories employing fewer than 250 workers. The Industrial Welfare Society has produced an illustrated brochure (4s. 6d. post free) entitled *Canteens in Industry*, which takes the form of a guide to the planning and management of these enterprises. It was first published at the beginning of the war and has now reached its sixth edition, incorporating a large amount of wartime experience. Suggestions are made concerning site, accommodation, lay-out, internal construction, lighting, heating, ventilation, furnishing, and colour scheme. There is a chapter on food and diet in which a number of useful hints are given, as, for example, the great food value of oily fish, such as the herring and mackerel; the need for making soups a substantial dish, of nourishing quality and distinctive flavour; the help of the friendly and filling dumpling; other accessories in making the available meat go; popularization of vegetables, especially the lesser-known value of salads, particularly if they include ingredient such as a good portion of potato or as an alternative to sweets; and also the value of supplementing minerals and vitamins.

GALL-BLADDER COMPLICATIONS FOLLOWING RESECTION OF STOMACH FOR PEPTIC ULCER*

BY

C. L. H. MAJOOR, M.D.

Department of Medicine and Röntgen Diagnosis

AND

Th. J. J. SUREN, M.D.

*Department of Surgery**(From the "Charitas" Hospital, Roosendaal, N.Br.,
The Netherlands)*

Abnormal conditions in the upper abdomen which may occur after resection of the stomach for peptic ulcer may be considered under several heads. A detailed investigation into the occurrence and frequency of gastro-jejunal ulcers would be outside the scope of this paper. Occasionally, during the past five years, we have observed severe haemorrhage following gastric resection, but on no occasion was there demonstrable radiological evidence of ulcer. It was noted that the patients rarely complained of pain. Symptoms arising from internal strangulation of the small intestine by abnormal hernial rings are less frequent (for literature, see Suren, 1941).

Of common occurrence are less serious complaints, often of a temporary nature, as observed by Wangenstein (1944). He did not encounter serious disorders or anastomotic ulcers. Poor appetite and a feeling of satiety are common, especially after partaking of liquid food. It would be incorrect to ascribe these phenomena to over-filling of a stomach of reduced capacity; for most radiologists are acquainted with the rapid emptying which follows resection. A reasonable presumption would be that the liquid either fills the afferent loop of the anastomosis or interferes with the flow of pancreatic biliary juices from that loop. Symptoms may conceivably arise in this manner, and they can be anticipated and prevented by advising the patients to eat dry food. It is an outstanding fact that porridge and milk no longer agree with patients who, prior to operation, had lived almost entirely on that diet. Frequently there is an aversion to fatty foods. Finally, some patients are troubled in the early post-operative period by regurgitation of fluid. It is inferred from these findings that the backward flow of bile is impeded in resections of the Billroth II type. In many instances the resulting complications are slight and of a temporary nature. They may, however, be serious.

Stolte (1942) carefully observed 333 cases of ulcer in the Department of Medicine of the "Onze Lieve Vrouwe" Hospital at Amsterdam. Of these 333 patients 83 had previously undergone gastric resection and 26 had had gastro-enterostomy. Stolte found that gastro-jejunal ulcer was a complication in eight of those resected and in ten of those with gastro-enterostomy. Further, 22 patients after resection and four after gastro-enterostomy continued to have symptoms; but in no case could gastro-jejunal ulcer be demonstrated with certainty. The number of patients with abdominal symptoms after operation on the stomach is remarkably large in this series. Their complaints were serious enough to warrant their admission to the medical clinic after they had been operated upon.

We are greatly impressed with the fact that in Stolte's series severe unaccountable symptoms following stomach

resection. His paper is dedicated to our friends and colleagues of the nursing expeditionary Force serving in the neighbourhood of Roosendaal in the winter of 1944-5.

operations were more frequent than those arising from proved anastomotic ulcers, and that they were proportionately more frequent after resection than after gastro-enterostomy. Stolte does not state whether he examined the gall-bladder in investigating his series. One sees a similar picture in a review by Kingma (1939) of 65 cases of primary resection operated upon according to the Billroth II method for perforated ulcer. Severe symptoms persisted in six cases; but in only one was gastro-jejunal ulcer (repeated haemorrhage) the probable diagnosis. In the remaining five the diagnosis was uncertain; four of the patients complained of pain and three found that fat did not agree with them. No special attention was paid to the gall-bladder in this investigation.

During the past few years we have learned that severe symptoms occurring after gastric resection by the Polya-Balfour-Reichel type of operation are frequently caused by gallstones. We have not found this fact stated in the literature which we have studied, nor do Wangenstein, Stolte, or Kingma mention it as a possibility. The following case is noteworthy.

An Illustrative Case

Mrs. B. (Case 1), aged 36, was admitted to hospital on April 20, 1943. She had suffered from symptoms referable to the stomach since she was 16. The symptoms had an obvious periodic incidence, and during two pregnancies they were entirely absent. Pain was mostly referred to the left side of the abdomen, was unrelated to the taking of food, and was manifest in attacks lasting for ten or fifteen minutes. The patient did not complain of heartburn, nor did she vomit. In 1938 the pain disappeared when she was given ambulatory treatment elsewhere. In 1942 there was a slight recurrence. Since the autumn of 1942 the patient was never really free from pain.

Nothing of note was discovered on general examination. Some not very dark bile was found on duodenal intubation and no cholesterol crystals were seen in the bile sediment. Test-meal findings showed: free HCl 15°; total acidity 20°. There were no abnormal findings in blood or urine. Radiological examination of stomach and duodenum revealed "kissing ulcers" of the duodenal bulb. After the oral administration of tetraiodo-phenolphthalein in fractions, two of 3 g., a fair-sized gall-bladder was observed, duly filled with dye and free from stones.

On May 5 partial gastrectomy of the Polya-Balfour-Reichel type was performed. The post-operative course was complicated by severe pulmonary embolism on the nineteenth post-operative day. This complication was confirmed by observing a pleural friction rub over the foremost part of the right lower lobe. On June 20 she was discharged from hospital.

On April 12, 1945, the patient reported sick again. After the operation she had remained symptom-free for six months, except for nausea after food. In November, 1943, she had a violent cramp-like pain in the epigastric region after drinking home-made liqueur. From October, 1944, the attacks of cramp became more frequent. The patient did not become jaundiced, nor did she notice any darkening of the urine. She vouchsafed the information that these attacks of pain were of more sudden onset and of greater severity than the pain experienced before the stomach operation. "It is not my stomach," were her words. The pain was localized to the left subcostal region and did not radiate. Physical examination was negative; the blood and urine were normal. The previous operation rendered duodenal intubation impracticable. Radiography of the gall-bladder, using "biliselctan," revealed that it did not fill. A diagnosis of gallstones was made.

Cholecystectomy was performed on April 13. The gall-bladder contained thick bile and more than a thousand small stones of varying sizes. The post-operative course was complicated by slight infiltration of the right lower lobe, which responded to sulphathiazole. On May 2 the patient was discharged from hospital, and when she reported for medical inspection on Jan. 21, 1946, was in excellent condition and

free from pain. Milk and milk puddings do not agree with her, but she tolerates all other foods, even fatty ones.

We are reasonably certain that the gall-bladder was normal at the time of the partial gastrectomy. The first symptoms, presumably due to the gall-bladder, appeared six months after the operation, and one naturally surmises that there was some relationship between the resection and the development of cholelithiasis.

experienced before the operation. The history of Case 2 is less definite: the colicky pains which she had before her gall-bladder operation had certainly never occurred before the resection. All patients now complained of attacks of pain of short duration, recurring at intervals, sometimes long and irregular. The pain was often localized to the upper abdomen and on the left side. Slight transient jaundice occurred once only (Case 5).

TABLE I.—Details of Six Cases

Observations on Six Cases

Further observations are given in Table I. In none of these cases have we any exact knowledge of the state of the gall-bladder before stomach resection. There are, however, certain pointers to the improbability that any gallstones were present at the time of operation. Symptoms arose in all cases after periods of 6 to 37 months of freedom from pain. Patients Nos. 1, 3, 4, 5, and 6 said most decidedly that the nature of the pain was quite different from that

We can put forward important arguments (unpublished data) favouring the hypothesis that all gallstones, in our part of the country at any rate (i.e., North Brabant area of South Holland), originate as minute cholesterol particles, which aggregate to mulberry-shaped stones. All the stones found in our six patients belonged to these very young formations. This fact is in accordance with our supposition that these stones have originated only after the resection. That relief from pain followed cholecystectomy is very

strong evidence that the gallstones were the cause of symptoms in the five patients who were operated upon.

The diagnosis of cholelithiasis was entertained only after much hesitation in respect of our earliest patients. From Table I it appears that the gall-bladder was not visible in the skiagrams of three out of five photographed patients. Jaundice was always lacking at first. Further, after partial gastrectomy duodenal intubation (the findings of which manoeuvre we consider valuable) is no longer applicable as an aid to diagnosis. At first we thought that the altered gastric properties, after gastrectomy, might interfere with the resorption of the contrast medium from the intestine. Later it became clear to us that oral cholecystography, even after gastrectomy, is a reliable procedure, and that a gall-bladder which is not filled—certainly after the examination is repeated—is strong evidence of the presence of gallstones. Sassen and Wijnen (personal communication) came to a similar conclusion when they examined radiologically the gall-bladders of a number of patients who had been operated upon by the Billroth II method. Normal filling of the gall-bladder was found in the great majority. These examinations were conducted for the purposes of information on patients without symptoms.

In order to estimate the incidence of gallstone formation following gastric resection we compare, in Table II, those cases observed after gastric resection with all gastrectomies for ulcer and all cholecystectomies performed for stones or inflammation in corresponding years. The first impression, no doubt, is that gallstones are so often encountered during operations for ulcer that their occurrence after a resection is a mere coincidence. The simultaneous occurrence of ulcer and gallstones was observed seven times (Table II, columns 3 and 4), although this association was not systematically sought for in 1943 and 1944. Gallstones following resection were observed only on six occasions. It is emphasized that the stones found together with ulcer were on four occasions of an old or very old type, and small cholesterol stones were present on three occasions. In this respect already the two series in Table II differ. The proportion of males to females also differs. The comparison is made in Table III.

TABLE III.—Incidence of Gallstones After Gastric Resection :
the Sexes Compared

	Cases	Female	Male	Ratio
				F. : M.
Gastrectomies on account of stones or inflammation	219	187	32	5.8 : 1
Operations on account of ulcer	174	30	144	1 : 4.8
Gallstones ascertained some months after resection for peptic ulcer	6	2	4	1 : 3
Gallstones found during resection for peptic ulcer	7	6	1	6 : 1

As in normal experience, there was a female preponderance in gall-bladder operations, and men had the larger share in stomach resections. In the group where stones were found at operation for ulcer the male/female ratio corresponds to that for the cholecystectomy group. In the group of gallstones following resection the male element predominates, approaching the male/female ratio for resections. Although our series is a small one and by no means conclusive there is presumptive evidence that in the condition of gallstones following resection for gastric ulcer the resection itself may play a part. The evidence becomes all the more certain when we bear in mind that of 32 males operated upon for gallstones in 3½ years three had already had resection of the stomach. (Our fourth male patient has not yet been operated upon and has not been included in this computation.) One out of ten males undergoing cholecystectomy had therefore had a previous stomach

operation. This high occurrence rate also suggests that the gastric resection may predispose to cholelithiasis. Nor can it be maintained that one male in ten in this part of Holland undergoes gastric resection.

Discussion

There are five arguments in support of our view that resection of the stomach by the Billroth II technique may cause gallstones to develop: (1) the striking observation in the case of Mr. B.; (2) the evident discrepancy in the symptoms of our six patients (who developed gallstone complaints after resection) before and after the stomach operation; (3) the discovery of young stones exclusively; (4) the distribution of our cases between the sexes; (5) the fact that the gallstone symptoms always appeared shortly after the resection (6–37 months) may point in the same direction.

Even if this thesis is acceptable there are some problems still outstanding. It is not clear in what way the resection predisposes to gallstone formation. It is easy to visualize altered duodenal flow and pressure being reflected in the biliary system. Such alterations may explain the vague nature of the symptoms after many resections. It is possible that the precipitation of cholesterol is facilitated under the new conditions. If this hypothesis should be substantiated it would be interesting to know if there is any incidence of gallstones after the Billroth I type of operation.

It is especially important to know if the manner of attachment of the jejunal loop has any bearing on the formation of gallstones. Among the six cases under discussion the efferent loop was attached to the greater curvature on at least five occasions. This procedure has the advantage of virtually preventing pinching-off of the small intestine (Suren, 1941; Kummer, 1941). If, however, the manoeuvre should involve the bile ducts in abnormal conditions it is doubtful if it would be wise to continue to use it.

It is difficult to understand why cases with gallstones following resection have not before been published. There was no mention of such a condition in the literature at our disposal. The diagnosis is undoubtedly difficult unless it is always considered. The symptoms in all our cases were of colic; but the localization was uncommon for biliary colic and only once was there any jaundice. All the patients were referred with the provisional diagnosis "stomach cramps." A striking instance in point was Case 6. Four weeks after gastrectomy (Oct. 15, 1943) this patient acquired a small post-incisional hernia which was symptomless. On Feb. 11, 1946, he had a violent attack of pain in the epigastrium. Strangulation of the hernia was suspected and he was sent to hospital. At the operation the gall-bladder was purposely inspected, and on finding that it was full of mulberry gallstones it was removed. We believe that more cases of gallstones following resection will be discovered if they are systematically investigated.

The history of another of our patients (P. v. E.) is illuminating in that gallstones were not found, although the symptom he presented suggested that probably they were present. He was born on March 12, 1917, and had had medical treatment for duodenal ulcer in 1939 and 1940 and gastrectomy on March 19, 1941, when he was found to have "kissing" ulcer of the duodenal bulb. The operation was after Polya-Balfour Reichel, the gastro-jejunal anastomosis being effected with efferent loop at the lesser curvature. On June 15, 1943, he reported as an out-patient with symptoms of epigastric pain which had been present for one and a half years. Skiagram showed a normal resection stomach without ulcer and a gall-bladder with moderate filling and without stones. A trial breakfast showed free acid 14°, total acidity 20°. On March 13, 1945, the investigations were repeated because of violent attacks of pain after taking milk, cabbage, peas, and beans. A fractional

test meal revealed no free acid. There were no obvious abnormalities of the stomach and gall-bladder on x-ray examination. Dietetic treatment was given. On Feb. 23, 1946, he reported again at the out-patient department. He had been free from symptoms for seven months, but during the preceding few weeks he had renewed attacks of pain, mostly after milk and porridge. Once more there was no abnormality of the gall-bladder. He was completely free of symptoms after some days of complete rest and frequent small meals with little fat and without milk.

Conclusions

From a total of 220 extirpations of the gall-bladder and 174 resections of the stomach over a period of 3½ years it was observed that gallstones occurred on six occasions shortly after a resection. As a result we believe that it is necessary, when patients complain of pain after resection, to look for the cause in the gall-bladder rather than the anastomosis. Some arguments support the view that the Billroth II type of operation may further the formation of gallstones.

DIATHERMY DISSECTION OF THE GALL-BLADDER

BY

R. J. McNEILL LOVE, M.S., F.R.C.S.

Surgeon, Royal Northern Hospital, London

Eight years ago I published, jointly, an illustrated article on Thorek's method of electrosurgical obliteration of the gall-bladder without drainage (Bailey and Love, 1939). Briefly, this entailed partial removal of the gall-bladder and coagulation by diathermy of the strip which was left *in situ* attached to the liver. The main advantage of this operation, as compared with the standard cholecystectomy, was that drainage was unnecessary. We reported a series of 129 consecutive and unselected cases with no mortality, and in only seven were there post-operative complications. These included four patients who developed infection of the abdominal wall, one whose wound broke down on the fourth day, and two cases of biliary fistula following drainage of the common bile duct. These fistulae eventually closed spontaneously. We mentioned that in some cases the gall-bladder possessed a more or less complete mesentery, so that it was possible to remove the entire organ without damage to the liver capsule. The gall-bladder bed was then coagulated with a diathermy button and the peritoneal edges were sutured over the exposed area. If the area was too wide to cover with peritoneum a detached piece of falciform ligament or an omental graft was sometimes tacked over the surface.

The very satisfactory results which followed the diathermy dissection of the gall-bladder in cases in which the organ was loosely attached to the liver prompted one to apply it as a routine in all cases suitable for a complete cholecystectomy. Exceptions are patients in whom a cholecystostomy is the more prudent measure, or occasionally the gall-bladder is so embedded in the liver that it is easier and safer to perform Thorek's operation.

Diathermy dissection of the gall-bladder is, as a rule, an easy operation, and differs from the standard cholecystectomy only in that, after identification and ligation

of the cystic duct and artery, a diathermy knife is used to divide the peritoneum on either side of the gall-bladder (Fig. 1). The viscus is then dissected from its bed with the diathermy knife, care being taken that the knife is applied to the gall-bladder rather than to the bed. Thus, Glisson's capsule is unlikely to be damaged, and subsequent seepage of bile and blood is reduced to a minimum. If necessary any raw areas from which bile or blood exudes are coagulated with a diathermy button (Fig. 2). During dissection of the gall-bladder from its bed a constant watch must be kept for the presence of a cholecysto-hepatic duct (Fig. 3). This is an uncommon anomaly—for example, Flint (1923), in his review of 200 cases of the anatomy of the bile ducts and vessels (in which only 69 followed the textbook description), did not record a case. Neuhof and Bloomfield (1945) describe two cases in which the duct measured about 2 mm. in diameter. In one case it was unrecognized, and a fistula resulted which closed in forty-five days, and in the other the duct was recognized at operation and closed with a purse-string suture. When the surgeon is satisfied that the gall-bladder bed is dry the area is covered by approximation of the peritoneal flaps, reinforced, if necessary, with a graft of omentum or falciform ligament. The wound is then closed without drainage.

Excluding cases in which drainage of the common bile duct, or very occasionally the gall-bladder bed, was considered necessary, I have during the past 10 years operated on 332 cases of gallstones. The procedures adopted were: cholecystostomy, 18; Thorek's operation, 81; diathermy dissection, 233.

Cholecystostomy was advisable in some cases of empyema of the gall-bladder, or when the viscus was buried in adhesions so that anatomical dissection was impracticable, especially if the patient was obese. In these cases safe surgery resolved itself into removal of calculi and drainage of the gall-bladder.

Thorek's operation was performed when the biliary tract could be exposed, so that the cystic duct and artery could be ligated with safety. When a fibrotic and contracted gall-bladder is partially buried in the liver removal of part of the viscus, with coagulation of the embedded portion, entails less risk than a complete cholecystectomy. It should be mentioned, however, that many of the early

FIG. 1.—Division of the peritoneum with a diathermy knife in dissection of the gall-bladder.

FIG. 2.—Coagulation of raw area with a diathermy button.

FIG. 3

cases in which Thorek's procedure was adopted would now, with increased experience, be dealt with by diathermy dissection.

Diathermy dissection was performed in 233 cases and two deaths occurred. The first fatality involved a somewhat feeble elderly male, who faded away a few days after the operation in what was apparently a combination of cholaemia, uraemia, and myocardial failure. The second fatality was due to failure to recognize the presence of a cholecysto-hepatic duct, and the history was as follows:

A woman aged 43 had a pre-operative diagnosis of gall-stones confirmed by a cholecystogram. The patient was somewhat obese, and the operation was rendered more difficult than usual, as adhesions between the diaphragm and upper surface of the liver prevented more than a moderate degree of rotation of that organ. However, there was not much difficulty in clearly exposing the junction of the cystic and common hepatic ducts, and the cystic duct and cystic artery were ligated in the usual manner. During diathermy dissection of the gall-bladder from its bed some discharge of bile was noticed, but this ceased when the raw area was coagulated with a diathermy button. Owing to the limited rotation inspection of the gall-bladder bed was somewhat restricted, but as it appeared to be dry the peritoneum was sutured over it and the wound was closed.

On the following day the patient complained of epigastric distress, and a tense swelling was obvious in this region. Some of the sutures were removed and sinus forceps introduced. About 15 oz. (425 ml.) of bile escaped, and a rubber drainage-tube was introduced. A biliary fistula developed, but there was no evidence of obstruction of the biliary ducts, and the faeces were well coloured. It was hoped that the fistula would close spontaneously, but after three months hope began to fade. It was proposed to temporize for another three months, and then, if necessary, dissect out the fistula and implant it into the jejunum. However, the patient developed menopausal melancholia, which was doubtless aggravated by her unfortunate condition. She became uncontrollable, constantly removing her dressings and making determined efforts to return to her home. Surgical intervention was obviously imperative, so the wound was reopened and the track of the fistula dissected from the abdominal wall and traced towards the under surface of the liver. The fistula was implanted in a loop of the upper jejunum. Three days later the wound broke down and the biliary discharge reappeared. The mental condition of the patient deteriorated and she died about one month later.

I was not at that time aware of the existence of the cholecysto-hepatic duct, and attributed the fistula to "slipping" of the ligature which was applied to the cystic duct. This was not very convincing, as the duct was easily notified and secured with No. 60 thread, which has a better frictional grip than catgut. On reviewing the case I now believe that the fistula was caused by division of an unrecognized cholecysto-hepatic duct.

Advantages of Diathermy Dissection

The average mortality of standard cholecystectomy in skilled hands is about 2%. Lung complications, including pulmonary embolus, account for the majority of fatalities. Both these conditions are predisposed to by restricted respiratory excursions. In the standard cholecystectomy a puddle of bile and blood collects beneath the diaphragm and the necessary drainage-tube causes further subphrenic irritation. Diaphragmatic spasm results, and inefficient aeration of the lungs predisposes to basal atelectasis. Also, as the piston-like action of the diaphragm is an important factor in maintaining an efficient venous circulation, impaired movements encourage venous stagnation, and associated risk of thrombosis and possible embolus accrues.

If Thorek's (1938) operation or diathermy dissection is employed, subphrenic irritation is reduced to a minimum. The risk of the above-mentioned complications is proportionately reduced, and the mortality is in the region

of 0.5%. In addition, convalescence proceeds more smoothly, tedious but non-lethal chest complications are uncommon, and thrombosis of the iliac or femoral veins is almost unknown. Also, the necessity for frequent removal of bile-soaked dressings is obviated, with the advantage that the patient is spared routine disturbances, and the time of the nursing staff is not occupied with the continual preparation of dressing trolleys. Finally, it is exceptional for the wound to heal other than by first intention.

Exploration of the Common Bile Duct

This procedure considerably increases the risk of the operation, and some authorities quote a mortality figure of 10% when drainage of the common duct is performed. The increased mortality is partly due to the fact that in many cases drainage is required when obstruction is present as a result of which cholangitis and cholaemia are often associated complications. In addition, the insertion of a T-shaped tube into the common bile duct is time-consuming and necessitates intricate manoeuvres under deep anaesthesia. However, palpation of the duct may reveal an obvious calculus which demands removal, and in other cases it is usually wise to explore the common duct if there have been attacks of colic or recurrent jaundice, or if obvious dilatation of the duct is discovered at operation. If exploration is necessary the cystic duct is usually slipped up and the incision carried into the common duct as far as required. Through the aperture the duct can be explored with a malleable probe, which, in the absence of obstruction should readily pass into the duodenum. Desjardin's forceps are useful for withdrawing calculi or debris from the duct.

At the operation doubt not infrequently arises as to whether the common bile duct should be explored or not. The surgeon is naturally averse to adding unnecessarily to the length and difficulty of the operation, but, on the other hand, it is even less desirable to overlook such a condition as a calculus impacted in the duct.

Choleldochography

This is a simple procedure which provides valuable information concerning the condition of the common bile duct. Information regarding the calibre of the duct, the discovery of a filling defect due to a calculus, and the presence of obstruction from other causes such as pancreatic compression are of value to the surgeon who is pondering on the necessity for exploring the common duct.

Technique.—It is preferable that the choleldochogram is taken before cholecystectomy is performed, as an intact cystic duct is more readily manipulated than a blind stump. Traction on the gall-bladder renders the cystic duct taut, and the wall is nicked with sharp-pointed scissors at a point about half an inch (1.25 cm.) from its fusion with the hepatic duct. A malleable cannula is the most suitable instrument for the introduction of the opaque medium, but an ordinary cannula or a short length of suitable rubber tubing may be used. The cannula, attached to a suitable syringe, is introduced through the cystic duct, and about 5 ml. of lipiodol is injected during a period of five seconds. As the last of the fluid is introduced the exposure is made and should be as short as possible. The film is ready for inspection within five minutes. It is important to remove metal retractors and unnecessary instruments from the field of operation immediately before the film is taken, otherwise opaque shadows may obscure the duct. During the interval of waiting the surgeon can perform appendicectomy if advisable, or else proceed with the gall-bladder dissection. In order to facilitate manipulation of the ducts the gall-bladder should be retained until a decision has

been reached as to the necessity for exploring the common duct. If exploration is deemed necessary the slit in the cystic duct is extended to permit the introduction of suitable instruments. In cases of infection or back pressure, drainage of the duct can be obtained, if necessary, by a T-shaped tube introduced through the opening. If exploration of the common duct is not required, then the cystic duct is divided and the distal end is ligated with silk or thread. Cholecystectomy is then performed.

By revealing a filling defect a choledochogram may prevent the surgeon from overlooking some condition which demands exploration of the duct. Thus a calculus may be more or less embedded in the wall of the duct and cause a appreciable obstruction to the passage of an instrument.

On the other hand, the choledochogram may indicate that although the duct is distended the lumen is patent, and consequently exploration is not necessary. Fig. 4 illustrates such a case: the duct was about three times the normal size, but lipiodol flowed freely into the duodenum. An unnecessary exploration was therefore avoided. The condition was due to subacute pancreatitis and consequent compression of the duct. Simple diathermy cholecystectomy was performed; the patient made a good recovery and has remained in good health.

FIG. 4.—Choledochogram showing distended duct and patent lumen.

Post-cholecystectomy Syndromes

After removal of the gall-bladder, and possibly a handful of stones, the patient naturally hopes to be rid of symptoms. But disappointments following cholecystectomy are not uncommon, though most of them are preventable or curable. Briefly, some of the more important causes of post-cholecystectomy syndrome are as follows:

1. A calculus, or calculi, may remain undetected in the hepatic or common duct and give rise to further attacks of biliary colic or obstruction. The hepatic duct should be explored if a stone is removed from the common duct, is retrograde migration of small calculi occasionally occurs. In some conditions, such as acholuric jaundice, small cinder-like stones are found in all the ducts, and irrigation of the hepatic duct is advisable in order to dislodge calculi which might not otherwise be detected. A choledochogram is a valuable precaution against overlooking a calculus in the common duct.

2. Chronic parenchymatous pancreatitis is often associated with infection of the biliary tract. Symptoms, including epigastric discomfort and flatulent dyspepsia, persist owing to deficiency of the external secretion, but they are relieved by the administration of a pancreatic preparation, such as "liquor pancreaticus," "panteric," or "pancrobilin." I referred to this syndrome many years ago (Love, 1933).

3. Spasm of the muscle of Oddi is alleged to be the cause of colicky pain which occasionally occurs after chole-

cystectomy. Cases apparently of this nature have been described by Maurice Lee (1946). Antispasmodics certainly relieve the symptoms, and pethidine, 25–50 mg., should be prescribed thrice daily, combined with an early morning saline aperient.

4. Dilatation of the stump of the cystic duct is apt to occur after cholecystectomy unless the duct is ligated within a quarter of an inch (0.6 cm.) of the common duct. Petersen (1946) records 42 cases, and states that the "re-formed gall-bladder" may be as large as a normal organ. I have on two occasions removed a single calculus from the stump of the cystic duct. In both cases intermittent jaundice was the predominant symptom, presumably due to exacerbations of infection around the stone and consequent pressure on the converging hepatic duct. A dilated cystic duct is usually buried in adhesions, and may be recognized only after probing through an incision in the common duct.

5. Conditions unrelated to the biliary apparatus may account for symptoms which persist after cholecystectomy. The appendix should always be removed during the operation of cholecystectomy, unless local conditions or the general condition of the patient preclude further operative intervention. The retention of a pathological appendix sometimes accounts for post-cholecystectomy symptoms. Presumably, when the gall-bladder is removed adjacent organs are scrutinized, in which case a peptic ulcer is recognized and receives appropriate treatment. Occasionally adhesions develop between the pylorus or duodenum and the gall-bladder bed. These are apt to cause angulation or even obstruction, but are unlikely to occur if the gall-bladder is removed by diathermy dissection.

Summary

When cholecystectomy is performed diathermy dissection of the gall-bladder is the method of choice. In the large majority of cases this is a simple and safe procedure, and the dry abdomen can be closed without drainage, with the great advantage that subphrenic irritation and consequent spasm of the diaphragm are reduced to a minimum. As compared with the standard operation chest complications and pulmonary embolism are much less common—a fact which is reflected in the lower mortality and reduced morbidity.

The technique and value of choledochography are discussed, and a summary is presented of some of the causes of post-operative persistence or recurrence of symptoms.

A report of the Joint Tuberculosis Council (copies may be obtained from the Hon. Sec., 1, Becket Street, Oxford) sets out its views on the organization of the tuberculosis service under the National Health Service Act. The Council advocates that the Minister of Health should appoint a Central Advisory Committee for Tuberculosis and that there should be at least one member on the Central Health Services Council with a special interest in tuberculosis. It suggests that the Minister should create a direct link between the Regional Hospital Authority and the Tuberculosis Dispensaries, and that the tuberculosis service should be co-ordinated on a Regional level, each Regional Board appointing a tuberculosis committee for that purpose. The board should also appoint a Regional tuberculosis physician. The Council emphasizes that the health visitors provided by local authorities should hold either the Certificate of the Tuberculosis Association or the Health Visitors' Certificate, or preferably both. Local health authorities should establish tuberculosis subcommittees empowered to delegate to local voluntary care committees some functions relating to prevention, care, and after-care. The Council regards such voluntary agencies as important in tuberculosis work.

THE LONGEST SPAN OF LIFE BASED ON THE RECORDS OF CENTENARIANS IN ENGLAND AND WALES

BY

V. KORENCHEVSKY, M.D.

From the Gerontological Research Unit, Oxford

In stating their aims and planning schemes of research contemporary gerontologists stress the primary importance of making old age stronger, "to add life to years, not just years to life." At present old age is considered to be a pathological condition because senile decay appears prematurely and is aggravated by disorders that are not necessarily associated with normal old age, such as arteriosclerosis, hypertension, "senile" heart, some degenerative changes of liver and kidneys, mental deterioration, certain metabolic disturbances and auto-intoxication, gastrointestinal auto-intoxication, hypertrophy of prostate, etc.

This problem of gerontology, however, cannot, for two reasons, be dissociated from the other gerontological problem—that of how to increase the span of human life. (1) Most old people cling very strongly to life. Old men have the same right to a normal and healthy existence as children or adults, even though their most useful period of life has ended. (2) Besides this factor there is a scientific reason. The development of science and medicine must proceed in spite of and with complete disregard to all possible complications of a social and political kind. For many scientists and medical research workers, the problem of ageing is fascinating not only because it affects the well-being of every man and woman, but also, and often chiefly, because it is one of the greatest and most fundamental mysteries and riddles in biology and medicine, because present old age is considered abnormal, and because if this is so this abnormal process of life has to be made normal. Science and medicine will not rest until they solve the riddle of what is normal ageing and normal old age and what is the normal span of life.

From the point of view of longevity, the centenarians of the past and the present are of especial interest because the length of their life indicates the limit which is theoretically and potentially possible for every human being. With reservations, investigation into their ancestry and progeny might be useful in solving the genetical causes of longevity, while an examination of their mode of living, and of the functioning of their organism, with a post-mortem investigation, might contribute to some other problems of gerontology and geriatrics.

Difficulties of Investigation

There are several difficulties in the scientific investigation of centenarians, particularly as to their exact age. The basic information should be obtained from certificates of birth and death, of which the former presents the greatest difficulty, since it is often absent or doubtful. Young (1899) has fully discussed this and some other difficulties.

In the present paper data on centenarians are given only from 1930 to 1945, it being presumed that in this period the information and documents were more accurate than in the previous years, since the people of this country have gradually been trained in this respect. These data have been obtained from the most reliable sources available—for

the years 1930 to 1937 from the Registrar-General's *Statistical Reviews* for England and Wales, and for the years 1938 to 1945, as a personal communication, from the Registrar-General's Office at Somerset House, London. The dates of birth, however, were not verified by birth certificates, but were obtained from the persons who registered the deaths, which fact decreases the value of the data. These data have been divided into two periods, each of 8 years—namely, 1930–37 and 1938–45—and are summarized in Tables I and II. Examination of the figures in these tables reveals at once a constant and obvious fact—that the number of women centenarians is considerably larger than that of men, being about 4.4 times greater in the first period and about 4.9 times greater in the second period (Table I). Further, in the second period the actu-

TABLE I.—Number of Centenarians for Each Year in Period I (1930–7) and Period II (1938–45)

Period I	No. of Centenarians		Period II	No. of Centenarians	
	Men	Women		Men	Women
1930	18	43	1938	16	93
1931	15	76	1939	22	90
1932	15	94	1940	20	102

Average per year	17.1	75.1	Average per year	18.5	90.6
Average per year per 20 millions of population	17.7	71.4	Average per year per 20 millions of population	18.3	83.4

TABLE II.—Total Number of Centenarians of Each Age in Periods I and II

Sex	Period	Age (years)										
		100	101	102	103	104	105	106	107	108	109	110
Men	I	59	31	21	14	9	2	1	—	—	—	—
	II	63	36	25	6	3	5	3	3	2	1	—
Women	I	264	155	81	46	22	20	5	3	4	1	—
	II	320	191	100	53	34	14	7	1	5	—	—

number of women centenarians is significantly greater ($P < 0.02$, Fisher's test for small samples) than that in the first period. The increase of male centenarians in the second period was only slight, and was statistically not significant.

Limits of Longevity

From Table II it is clear that longevity of human being might extend up to 109 and even 112 years. The age of 106–112 years has been reached by 11 (3.9%) out of 28 male centenarians and by 26 (about 2%) out of 1,326 female centenarians—that is, from both sexes a slightly large relative proportion of men reached the oldest age. In favour of these data being of considerable value and comparative reliability is the fact that in each period investigated the annual figures of centenarians (Table I) are more or less constant, both for men and for women.

When calculated per year and per unit of the population (Table I), for 20 millions of men or women there were 17.1 male centenarians and 71.4 female centenarians in period I and 18.3 and 83.4 respectively in period II. This fact indicates that the increase in the number of centenarians in period II cannot be explained by an increased population only, but appears also to be connected with increased longevity.

Ernest (1938), reviewing all the cases of centenarians which have been critically investigated by different authors and by himself, concludes that the longest reported span of human life was trustworthy in four cases only. "Two

I should like to express my gratitude to Lord Nuffield for the grant which has made possible the establishment and work of the Gerontological Research Unit, and to Oxford University, Prof. A. C. Hardy, and Prof. E. G. T. Liddell for the kind hospitality extended to the Unit in the Departments of Zoology and Physiology.

of these four people lived over 110, one was nearly 112, and one over 113 years at death" (p. 55), residing in the U.S.A., Guernsey, Ireland, and Canada respectively. All the other cases of greater longevity reported in the literature, scientific and non-scientific, cannot be accepted as trustworthy. The distinguished Swedish gerontologist G. Backman (1945) also concludes that 113 years could be taken as the accurate age of the longest span of human life recorded, but that 125 years might perhaps be expected. Prof. I. Fisher (1923, p. 112), of Yale University, reports a comparatively recent case of life up to 120 years in Oregon, U.S.A., the case having been investigated by the Oregon Historical Society.

Prolongation of Life in the Future

As to the possible prolongation of human life in future beyond the extremity already reached by some centenarians (113 years), the scientists who studied this problem give different prophecies. Prof. Warthin (1929), of Michigan University, emphasizes that, according to the data of the U.S.A. Census Reports, "the increase in the average longevity is due to the saving of life through the prevention of extrinsic pathological death in the earlier decades of life, but that there has been no extension of the normal or biologic life limit" (pp. 166-7). "It is therefore neither possible nor probable that the average longevity can be raised to the heights prophesied by the over-zealous and very inaccurate advocates of life extension" (p. 170). Warthin in this case refers to an extension of life up to 125-140 years.

Metchnikoff (1907), on the contrary, says that "we may predict that when science occupies the preponderating place in human society that it ought to have, and when knowledge of hygiene is more advanced, human life will become much longer" (pp. 226-7).

Prof. Fisher (1923) concludes that "it would be surprising if the future should not witness a further lengthening of human life, and at an increasing rate. Of course, there is a limit to the further increase of human life, but there is good reason to believe that the limit is still far off" (p. 103). "If . . . notwithstanding all existing chances of death, it is possible for some persons to live beyond 120, the chances in the future for a larger proportion of such persons will be materially improved" (p. 112).

Prof. Simms (1946), of Columbia University, states that "there is at the time no proof for or against the possibility that we can some day extend our active life an extra one hundred or two hundred years, with retention of youthful health, intelligence, and appearance" (p. 24).

A scientific and medical investigation of the span of centenarian life might, as already mentioned, be of great importance from several points of view. For example, histories of two long-lived families described by Weber

(1919) indicate heredity as one of the causative factors of longevity. His tables on pages 21 and 23 give the respective data of the span of life of the brothers and sisters in these two families. These tables are abbreviated and pooled in Table III of the present paper.

A Social Problem

The question of centenarians is closely connected with one of the gravest social problems of our days—namely, the growing proportion of old people in the population. In the excellent report of the Nuffield Foundation (Rowntree, 1947) this is illustrated by a table (p. 3) prepared by W. A. B. Hopkin, a member of the staff of the Royal Commission on Population. The abbreviated data from this table are given in Table IV of the present paper. From

TABLE IV.—Population of England and Wales by Three Main Groups (thousands). (Abbreviated from Rowntree's Report, 1947, p. 3)

Year	Age			Total Population
	Under 15	Men, 15-64; Women, 15-59	Men 65, Women 60, and over	
1944	8,671	28,382	5,396	42,449
1954	9,036	28,080	6,143	43,309
1964	8,440	27,894	6,811	43,145
1974	8,051	26,692	7,804	42,577
1984	8,043	25,547	7,944	41,534
1989	7,886	25,071	7,848	40,805
1994	7,679	24,872	7,504	40,055

this table it is estimated that by 1989 the number of old people of pensionable age will equal the number of children, while by the same year the number of persons of working age will be approximately three millions less than in 1946. The report adds (p. 2): "The trend revealed in Mr. Hopkin's figures may, however, be even more pronounced than the table suggests; for other authorities, among them the Registrar-General, have forecast that as early as 1971 the number of persons of pensionable age may equal, or even exceed, the number of children."

This position is considered to be very serious because at present helpless old people become a great burden on the younger working population. Such a position, however, will not necessarily be the same in future, as Metchnikoff and Fisher emphasize. It is probable that medicine and science will not only add years to the life of an old man but simultaneously will conserve his physical and mental vigour for a longer period. "One result of lengthening life will be a greater utilization of accumulated experience. We shall have less immaturity in judgment. . . . It will give to society a body of old yet hale men of experience, whose influence and worth cannot be measured" (Fisher, 1923, p. 111).

Conclusions

In the data recorded in the Registrar-General's Office the certificates of birth of centenarians have not been checked, and therefore their age can be accepted only with some reservation. Since, however, these data were investigated during the latest period of 16 years, and as the figures investigated were constant in character, their value and reliability are probably still considerable.

According to these data, in England and Wales per 20 millions of male or female population there were each year on the average 17.7 male and 71.4 female centenarians in the period 1930-7, and 18.3 and 83.4 respectively in the period of 1938-45. Thus, unexpectedly, their incidence was regular and not very exceptional, and more women had a long span of life than men.

There was a statistically significant increase of female centenarians during the last eight years as compared with

a previous period of eight years, while a small increase in male centenarians in the last period was not significant.

During these periods the longest human lives recorded were 109 and 112 years, and this fact is in approximate accord with the conclusions reached by previous critical investigators for periods earlier than 1930.

Thus, theoretically and potentially, a span of life of 109-112 appears to be possible for a human being. As, however, the exceptional cases of longevity of human beings have occurred during the present time, when the process of ageing is abnormal, there is some possibility that the span of human life might be further extended when the process of ageing becomes a normal one.

There are some indications that the genetic factor is one of the causal factors of longevity.

Taking into consideration the primary aim of gerontology to make old age stronger and healthier, and not only longer, the prophecy of Metchnikoff and Fisher may be right—that in this way the *useful* period of human life might be extended and the community benefit by a greater utilization of the accumulated experience and wisdom of older people.

It is most desirable that scientific and medical investigation of cases of centenarians should be carried out by research workers.

I wish to express my gratitude to the Registrar-General and his Office, in particular to Mr. A. A. Dodge, for supplying me with all necessary data concerning published and unpublished cases of centenarians.

Medical Memoranda

Relief of Pain in Childbirth

While acting as house-surgeons in Maryfield Hospital, Dundee, we obtained permission to try the administration of phenobarbitone and rectal ether for the relief of pain in childbirth as outlined by C. B. Lull and R. A. Hingson (1945).

The technique adopted was to give the patient a 5% sodium bicarbonate enema on admission. When her pains began to make her uncomfortable she was given 3 gr. (0.2 g.) of phenobarbitone, which was repeated in 1½ gr. (0.1 g.) doses as required. As soon as the pains became distressing—usually towards the end of the first stage—2½ oz. (70 ml.) of ether in 1½ oz. (42 ml.) of olive oil or mineral oil was administered rectally. This enema was given slowly, with the patient on the left side, care being taken to pass the catheter above the presenting part. This makes the patient feel very drowsy within a few minutes, the effect lasting for two to four hours. The rectal ether can be repeated in two hours if the effect is wearing off. If the patient is exhausted or it is suspected that the labour will be prolonged, 2 dr. (7 ml.) of paraldehyde may be added to the rectal instillation to produce a deeper sedative action.

Results.—In our series of twenty-five cases, mostly of primigravidae, we found that all received relief from this

treatment. All slept between their pains and also used their pains well. The multiparae admitted it was the easiest labour they had had, several of them requiring to be reassured that their baby had been born.

Actions on the Mother.—(1) Restlessness and distress were relieved so that they relaxed well between pains. They were in a state which was highly responsive to suggestion, and obeyed the instructions given by the attendant. (2) The pains continued with the strength and frequency which would have been expected if rectal ether had not been administered. (3) The pelvic floor relaxed well and the head advanced quickly. (4) The third stage was short, the average duration being 12 minutes, and after expulsion of the placenta the uterus contracted firmly and there was no case of post-partum haemorrhage. (5) The patients co-operated so well during the birth of the head that only three out of twenty-five required a perineal stitch. (6) There was no increase in the forceps rate.

Effect on the Foetus.—Every child cried immediately at birth, and was in no way affected by the sedation.

In conclusion, we found this method very satisfactory; it is safe for both mother and child, it is easy to administer, and it does not prolong labour.

Safety-pin in Larynx for Five Weeks

The presence of an open safety-pin in the larynx of a 2-year-old child for over five weeks seems unusual enough to warrant record.

CASE REPORT

On April 13, 1946, a practitioner was called to see a small boy aged 2 who was reported to have had some dyspnoea during the night. He was over-quiet and pointed to his throat. He cried when the throat was examined. The practitioner described the cry as "croupous and husky." Nothing abnormal was found in the throat or chest. The temperature, pulse, and respirations were normal. The next day there was some dyspnoea and a croupous distressing cough. Laryngeal diphtheria was suspected; 800 units of antitoxin were given and the child was sent to a fever hospital. He had been immunized previously.

On admission he was given 40,000 units of antidiphtheritic serum, but the medical superintendent did not consider it was a case of diphtheria; he suspected an early pneumonia, though signs in the chest were absent. The respiration was increased and there was difficulty in getting him to take food. Negative swabs were obtained from the nose and throat on April 14, 15, and 16. The patient was fairly comfortable till April 24, when symptoms of obstruction arose. He was put in a steam tent, but did not improve, and in view of the increasing dyspnoea tracheotomy was performed the next day. During the following two weeks various attempts to remove the tube were made, but without success.

I first saw him on May 10. He was quite unable to breathe through the larynx. There was no cry. An attempt at laryngoscopy with inadequate instruments showed a mass in the larynx. The child was transferred to a nursing home and a direct laryngoscopy was performed on May 21. The larynx was filled with a mass of granulation tissue. When this was probed a foreign body was seen. It looked like a coin, but gentle traction showed that it was fixed, especially at the posterior end. The anterior end was gently pulled on and the body removed. It proved to be an open brass safety-pin 7/8 in. (2.2 cm.) long. During the next fortnight the tube was changed daily, but there was still no airway through the larynx. Direct laryngoscopy showed the swelling to be much smaller, and the left vocal cord was visible. A few days later he cried for the first time, and in a day or two began to say a few words, and was soon talking freely, with the tube corked. The tube was finally removed on June 20, a month after the operation. A week later he went home looking fit and well and talking freely and, for his age, clearly. I saw him again in October and found him quite well, and breathing and talking normally.

I am indebted to the doctors in charge of the case for details of the early history.

RHEUMATOLOGY

Medical Disorders of the Locomotor System, Including the Rheumatic Diseases. By Ernest Fletcher, M.D., M.R.C.P. (Pp. 625; 262 figures. 45s., plus 8d. postage.) Edinburgh: E. and S. Livingstone. 1947.

is admirably documented and illustrated textbook of the rheumatic diseases, including a chapter on medical cases of bone, provides many references to the large amount of work being done on the subject, but the reiteration of perhaps it may be "or" "we suspect that" shows how obscure the subject is and how incomplete our knowledge. The probational aetiology of these conditions precludes satisfactory classification, and it is possible to arrange them only in broad general divisions. The author has entrusted certain sections to other specialists—for example, that on fibrositis to Dr. Copeman and on radiology to Dr. Campbell Golding—but for the most part he writes from his own experience backed by study of the literature.

After preliminary chapters on anatomy and physiology, general aetiological factors, and radiology the author discusses acute rheumatism, and emphasizes the value of Coburn's massive doses of salicylates and sulphonamide prophylaxis as practised in the American Army. He then considers its relationship to chorea and the possibility of acute rheumatism and rheumatoid arthritis being variants of the same disease; his observations on the aetiology of the latter reveal how difficult the problem is. He advocates the sanatorium regime for the treatment of rheumatoid arthritis and gives a full account of gold therapy. He then discusses the nodule and its significance, minutely describing the variety with the necrotic centre, which is characteristic of both rheumatism and rheumatoid arthritis. Writing of osteoarthritis he does not favour the infective theory of its origin. The injection of joints with lipiodol may be beneficial. The author attaches more importance to osteoarthritis of the spine as causing obscure pain than do some authorities.

Discussing fibrositis Copeman points out that the establishment in the course of any infection of "trigger points," which may in some cases persist and be reactivated, may explain its manifestations. He also describes his investigations into tender irradiated fat lobules. The specific arthritides and gout are adequately discussed and there are excellent chapters on the possible causes of sciatic and brachial neuralgia, for which the author on the whole prefers conservative treatment. There are also discussions on pain and stiffness in the shoulder, back, and foot, and a final chapter on physical treatment. Spa treatment is only briefly mentioned for fibrositis and not at all for chronic gout. This book is a credit to British rheumatology and indispensable to specialists in the subject.

SYMPATHETIC NERVE INFILTRATION

Les Infiltrations du Sympathique. Physiologie—Indications—Techniques. By Maurice Luzuy. Preface by Prof. René Leriche. (Pp. 200; 24 figures. 375 francs.) Paris: Masson et Cie. 1946.

Dr. Luzuy records in this book his study of the effects of cocaine (novocain) on sympathetic nerves. He discusses in detail the technique of and indications for sympathetic block, and the deductions which he has made and applied to the theory of sympathetic, cardiovascular, and visceral physiology and pathology. Prof. Leriche contributes a happily worded preface—and most suitably, for the methods and opinions of the book correspond closely to his own.

The technique described for the infiltration of each sympathetic area accords in general with the usual Anglo-American practice, but the author advocates a lateral path for the approach to the stellate ganglion, an anterior method for the infiltration of the carotid sinus, and Cotte's transvaginal approach for the injection of the hypogastric ganglion. Arnulf's method of infiltrating the preaortic plexus from the roof of the neck, fully described, is not yet widely practised in this country. The first section of the book covers the effects of trauma. The author describes the efficacy of local infiltration anaesthesia in permanently relieving sprains of joints to an interruption in those

antidromic sympathetic vasodilatation influences which are said to be responsible for the symptoms of a sprain, and he attributes the later effects of trauma, including post-traumatic cyanosis, oedema, osteoporosis, and hypercalcification, to sympathetic disturbance and treats them successfully also by sympathetic block, though at a higher level, by infiltration of the appropriate sympathetic ganglion. The field covered by the second section, the application of sympathetic block to vascular disease, is that in which, more than in any other perhaps, surgery has been advanced by the school of Leriche, and Dr. Luzuy's arguments are well considered.

The evidence offered in the third section of the effect of splanchnic block in congenital pyloric stenosis, megaduodenum, acute dilatation of the stomach, gastric ptosis and atony, peptic ulcer, gall-bladder stasis, constipation, intestinal obstruction and strangulation, acute pancreatitis, and diabetes will not unreservedly convince all readers; and the records of the six patients treated by infiltration of the preaortic plexus for coronary disease do not fully prove the efficacy of that measure. The book ends with a description of the method of intravenous procaine injection and its success in the treatment of asthma. As Prof. Leriche explains in his preface, Dr. Luzuy is an enthusiast, and this book gains by that quality in vivacity what it loses in detachment.

IAN AIRD.

THE ROTUNDA

The Rotunda Hospital, 1745-1945. By O'Donell T. D. Browne, M.B., M.A.O., F.R.C.P., F.R.C.O.G. (Pp. 296; 44 illustrations, a synopsis, and graph. 42s.) Edinburgh: E. and S. Livingstone. 1947.

Bartholomew Mosse opened the Dublin Lying-in Hospital for Poor Women on March 15, 1745. He died suddenly in 1759 at the age of 47. He had envisaged a "large impressive and suitable place of entertainment" alongside the hospital, but did not live to see the completion of the Round Room in 1767. From then on the name "Rotunda" was adopted, and the Rotunda Hospital embarks next week on the bicentenary celebrations which the war postponed.

Dr. O'Donell Browne has given a detailed account of the development of the hospital and of the contributions to obstetrics made by its Masters, setting his local theme against the wider background of the general history of midwifery. His book has six sections, each with its own references: the first 100 years; the second 100 years; the struggle against puerperal fever; operative midwifery; anaesthesia and gynaecology; eclampsia. This arbitrary division is unfortunate, and a great deal of dull detail makes the first two parts of the book heavy going. It involves repetition in each section, and it makes it difficult to assess the standing of any one Master, since his activities and the changes he brought about may be discussed under six different headings. This criticism may have been made at an earlier stage and may account for a final chapter listing the outstanding Masters. No one would quarrel with Dr. Browne's view that Mosse was the greatest Rotunda Master, and Fielding Ould, Clarke, Labatt, Collins, Maçan, Smyly, and Tweed worthy successors. It is good to know that there were once 72 gallons of whiskey in one hospital, and at a cost of only £9 15s., but salaries and allowances for officers and servants are of less interest, and no one can make the minutiae of redecorations and extensions lively reading.

The section on eclampsia is better, and so is that on puerperal fever, though it is difficult to justify the equal emphasis on Oliver Wendell Holmes and Ignaz Semmelweis. Discussing operative midwifery and gynaecology, Dr. Browne has assessed fairly those fields in which the Rotunda advanced steadily and those in which it lagged through excessive conservatism. In his account of the application of anaesthesia to midwifery Dr. Browne has been uncritical. For much of his material he has obviously gone back to the original documents. Here he has copied a venerable error. "Simpson was knighted in 1870. His friend, Sir Walter Scott, wrote advising him that he should have as coat-of-arms 'a wee naked bairn' with the inscription: 'Does your mother know you're out?'" Sir Walter Scott died in 1832. These are minor criticisms of a book so well produced that it deserved better proof-reading. There may be argument about Dupey or Dupuy and about Ségault or Sigault, but the first Assistant Master to perform a successful caesarean hysterectomy in a patient's home ought not to be Bagot on one page

and Baggot later. There is probably nothing significant in the history of the Rotunda not included in Dr. Browne's story or in his excellent synopsis. His illustrations are numerous, well chosen, and well reproduced. Medical historians will find his book useful, but a shorter version with more carefully selected and differently presented material would appeal to a much wider circle of readers.

THE N.H.S. ACT

The National Health Service Act, 1946. Being the Complete Text of the National Health Service Act, 1946, with an Introductory Explanation of the Act. By J. A. Scott, M.D., D.P.H. Together with an Index to the Act compiled by H. A. C. Sturgess. (Pp. 93. 9s. 6d.) London: Eyre and Spottiswoode (Publishers), Ltd.

Two-thirds of this volume reproduce the text of the Act, the remaining third being shared equally by an introductory section, a summary of the Act, and an index to the Act. In the introductory section the author briefly considers the Government's social legislation for preventing individual poverty, and he sketches the main principles of the National Insurance, the National Insurance (Industrial Injuries), and the Family Allowance Act. Under the title "The planning proposals of the medical profession" he includes a paragraph on the B.M.A. proposals for a General Medical Service for the Nation and a summary of the Draft Interim Report of the Medical Planning Commission (1942). There follows a section in which health centres, including the model centre suggested by the Commission, are discussed at some length, and with the author's personal observations on the health centre concept thrown in. He stresses two trends in modern medicine: first, a strong desire to combine preventive and therapeutic work, and secondly a tendency for child health and maternal care to become separate specialties in the hands of different sections of the profession. In discussing the staffing of the "public health" part of health centres he contemplates that many of the whole-time officers engaged in maternity and child welfare and school medicine will wish to continue with their present work, and to that extent both general practitioners and specialists may only gradually have the opportunity to take part in the work, but "there is no inherent reason why the general practitioner with suitable experience should not undertake it, as he wishes to do." Notes on (1) the areas of Regional Hospital Boards, (2) the regional hospital surveys, and (3) the original White Paper on a national health service issued by the Coalition Government, in this somewhat topsy-turvy order, complete the introductory section.

In Part II he summarizes objectively and concisely the main provisions of the Act. It will be welcomed by those who seek a broad picture of the scheme. For the most part he avoids the pitfalls inherent in the translation of the Act's legal terminology into lighter and less tiresome reading. In two minor instances, however, the summarized version may be misconstrued in relation to the text of the Act. On page 25 it is stated: "Lists of medical practitioners providing general medical services will be published, and every doctor (who is not a paid assistant) in practice before the appointed day who duly applies is entitled to have his name on the list." The right of the practising doctor to have his name on the list is limited to the list of "the Executive Council for any area in which he is practising." On page 26 it is stated: "It is a duty of every Executive Council to arrange for the supply of drugs, medicines, and appliances from health centres or otherwise to everyone in the area entitled to general medical and dental services." The terms of clause 38 of the Act do not extend to everyone in the area entitled to general medical or dental services but to persons in the area receiving those services. From clause 38 (2) it appears that the Executive Council's arrangements are to ensure for those persons the supply of "proper and sufficient drugs and medicines and prescribed appliances" if ordered by the medical practitioner rendering general medical services (or by the dental practitioner in the case of general dental services). The index is masterly and certainly the most valuable part of the book.

The 1947 edition of the *Medical Register* has recently been published (22s., post free). Particulars given in tabular form reveal that on Dec. 31, 1946, there were 76,292 names on the Register—nearly half as many again as in 1927, when there were 53,591. In 1946 2,237 names were added and 1,092 removed for various reasons.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Diseases of Children's Eyes. By J. H. Doggart, M.A., M.D., F.R.C.S. (Pp. 288. 42s.) London: Henry Kimpton. 1947.

After discussing principles of examination, anatomy, developmental errors, and methods of treatment, the author considers eye diseases in children and their treatment. Many coloured illustrations.

Old Age and How to Make the Best of It. By R. A. Bennett, M.D. (Pp. 23. 2s. 6d.) Bristol: John Wright and Sons. 1947.

Comments, with quotations from the classics, on growing old.

Current Therapies of Personality Disorders. Ed. by Bernard Glueck, M.D. (Pp. 296. 17s. 6d.) London: William Heinemann. 1946.

Evaluation of various methods of psychotherapy by a number of different authors.

History of the Abolition of State Regulation of Prostitution. By Mme. Legrand-Falco. (Pp. 30. 1s. 6d.) London: The Association for Moral and Social Hygiene. 1946.

The history in France is referred to particularly.

Laboratory Instructions in Biochemistry. By I. S. Kleiner, Ph.D., and L. B. Doti, Ph.D. 2nd ed. (Pp. 245. 12s. 6d.) London: Henry Kimpton. 1946.

A manual of practical biochemistry for use in the laboratory, with space for notes.

Nozioni di Immunologia. By Prof. E. Carlinfanti. (Pp. 760. No price given.) Milan: Istituto Sieroterapico Milanese Serafino Belfanti Editore.

An account of antigen-antibody reactions in diagnosis, therapy, and prophylaxis.

Recopilacion de Leyes, Reglamentaciones, Decretos y Resoluciones Sanitarias. Published by the Argentine Ministry of the Interior, Direccion Nacional de Salud Publica. (Pp. 928. No price.) Buenos Aires: Imprenta de la Camara de Diputados. 1945.

Laws relating to public health in Argentina.

Jubilee Volume. Dedicated to Emil Christoph Barell by the Scientific Workers of the Roche Companies. (Pp. 468. No price.) Basle: F. Hoffmann-La Roche. 1946.

Includes papers on the synthesis of certain vitamins and other compounds, on the furans, and on antibiotics.

Dolores Mortales. By Dr. Miguel Lopez Esnaurrizar. (Pp. 65. \$15 M.M.) Ueha, Mexico: Editorial Gonzalez Porto. 1947.

A monograph on the conduction of pain impulses by the autonomic nervous system.

La Douleur. By Dr. Paul Chauchard. (Pp. 128. No price.) Paris: Presses Universitaires de France. 1947.

A study of pain as a protective mechanism.

Food Inspection Notes. By H. Hill, F.R.San.I., and E. Dods-worth, M.R.San.I. 2nd ed. (Pp. 125. 6s.) London: H. K. Lewis. 1947.

A summary for public health students of the properties of healthy and diseased foodstuffs.

The Problem of Fertility. Ed. by Earl T. Engle. (Pp. 254. 21s.) Princeton University Press (London: Geoffrey Cumberlege). 1947.

A collection of papers on the factors affecting fertility in man and in animals.

Textbook of Surgical Treatment. Ed. by C. F. W. Illingworth, C.B.E., M.D., Ch.M., F.R.C.S. Ed. 3rd ed. (Pp. 644. 32s. 6d.) Edinburgh: E. and S. Livingstone. 1947.

Includes new sections on wound infections, penicillin in surgery, plastic surgery, facio-maxillary injuries, the use of protein in surgery, and the anticoagulant treatment of thrombosis.

Notes on Clinical Laboratory Methods By the Standing Committee on Laboratory Methods, University of Glasgow. 5th ed. revised. (Pp. 95. 3s. 6d.) Glasgow: John Smith. 1947.

An outline of laboratory methods in clinical medicine for medical students.

SATURDAY JULY 5 1947

THE SPREAD OF STAPHYLOCOCCAL
INFECTION

It is a truism that the control of epidemic infection must be based on exact knowledge of the paths of its spread. These have been fairly well known for many years in connexion with some infections. At the opposite extreme they remain conjectural even now in the case of certain virus diseases, because the presence of the agent in different materials cannot be demonstrated by any simple test. A special position is occupied by infections due to common bacteria of wide distribution, because their mere presence is not necessarily connected with a particular epidemic. Unless the epidemic strain has some special characteristic, it is impossible to decide whether, for instance, a carrier of the species concerned is to be incriminated. It is here that the definition of individual "types" within species has been found so valuable. The separation of such types, and epidemiological studies based on them, form a profitable pursuit in which workers in this country have led the world. Almost all that we know with certainty about the epidemiology of streptococcal infections is based on the determination of types defined by the late Frederick Griffith. McLeod's types of *C. diphtheriae* have also been helpful, and recently the phage typing of *Salmonella typhi* and of *Staphylococcus aureus* have enabled other workers to trace the sources of epidemics which could not otherwise have been elucidated.

Perhaps the most forbidding task of all has been to disentangle the migrations of staphylococci, particularly under institutional conditions. These organisms are so widespread that it might seem impossible to trace them to their source, even under conditions of epidemic spread. An opportunity for attempting this is furnished by outbreaks of pemphigus neonatorum among infants in maternity homes. These are not uncommon, and they are usually followed by wholesale swabbing and the resultant discovery of numerous carriers among patients and staff. Anyone who, having obtained such information, has then been somewhat at a loss to know how to interpret or act on it will be grateful to V. D. Allison and Betty C. Hobbs, whose paper appears in the opening pages of this issue, for having pursued such an investigation so thoroughly as to reach definite conclusions about the mode of spread of the epidemic. To enable such conclusions to be drawn, typing of the strains isolated was essential. The method employed was serological, based on the original types defined by Cowan, and the identity of a number of strains defined by this method was confirmed by phage typing.

This study was pursued over a period of two years in a large maternity home at Cardiff, and during this time in

three outbreaks there were 107 cases of pemphigus and 21 of staphylococcal conjunctivitis. The majority of cases in each outbreak were due to a single serological type; possible sources of infection could therefore be identified with some certainty. The organism concerned was found to be exceedingly widespread. It was recovered sometimes from air or dust, and from blankets and clothing. Among human sources the mothers could be excluded in the majority of cases, only 6 out of 15 being found to harbour the same type of staphylococcus. On the other hand, swabbing of the nursery staff on several occasions revealed a large proportion of nasal carriers, many of whom were infected with the same type as that producing pemphigus in the infants. Whether this state of affairs was a cause or an effect might have been uncertain had not swabs been taken from the staff at the beginning of the third epidemic, when only a single case of pemphigus had occurred. At this early stage no fewer than 18 (37.5%) of the nursery staff were already nasal carriers of type 1 *Staph. pyogenes*, the cause of the epidemic which followed. As the authors remark, this observation strongly suggests that a "build-up of nasal carriers of a potentially infective strain occurs among the staff before the appearance of cases of pemphigus." If this is indeed the mechanism underlying such outbreaks, it is at least practicable to define appropriate precautions. It is noteworthy that among the staff there was no skin carrier who was not also a nasal carrier; in other words, the ultimate source in the carrier is nearly always the nose, and the most elementary of all precautions is to obviate contamination of the hands from that source. Is it yet generally understood among nurses that the use of a handkerchief should be followed by thorough washing of the hands?

Other measures which may materially assist in protecting infants from infection are discussed in this paper. Overcrowding, which was evidently a factor in the first of the outbreaks described here, must obviously be avoided, and good ventilation and lighting are necessary. Measures to allay dust are important, as in cross-infection of almost all kinds; in particular ordinary dry sweeping is to be condemned and a vacuum cleaner or damp dusting substituted. Then there are many technical details connected with the nursing care of infants which require regulation with the possibilities of cross-infection in mind, such as the sterilization of baths, and the use of separate toilet outfits and towels for each infant. The highly trained nurse will instinctively conform to such practices; for pupils the rules need to be precise and rigidly enforced. The authors make the interesting suggestion that infants would perhaps be better off with their mothers than congregated in a room separate from them, a system which can be commended from other points of view (see page 20). The treatment of carriers with sulphathiazole snuff has proved disappointing, and it is apparently concluded that attempts to clear up carriers by such means are not worth while. The addition of calcium penicillin to sulphathiazole used as snuff greatly reinforces its action, and the use of this mixture is worth considering if in any individual case it is deemed important to abolish the carrier condition. This paper with its very practical conclusions will be welcomed by those who have had to deal with such troubles in maternity

homes. So elaborate a form of investigation is rarely possible, but when once carried out with such thoroughness it almost removes the necessity for further efforts on the same lines.

NEONATAL INFECTIONS

The stress which is now placed upon the prevention of ill-health, especially in young children, has caused renewed attention to be given to certain diseases and abnormalities which in the past have received only sporadic consideration in medical literature and have seldom aroused more than a local and temporary interest. Neonatal infection is a case in point; and the recent Report¹ prepared by a highly competent subcommittee of the Scientific Advisory Committee to the Department of Health for Scotland is an important document, not only for its detailed and very practical recommendations for the prevention of such infections but because it focuses attention upon the conditions which endanger newly born babies, especially in maternity institutions, and upon the characteristic features of infective processes in the early weeks of life. There is no period in the whole life of man, from fertilization of the ovum to old age, when he is safe from the threat of bacterial assault; but the circumstances in which the warfare begins and is pursued, the constitution of the armies engaged, and the probable course of the battle vary materially from phase to phase of the person's life. In so far as neonatal infection is concerned it is well known that unhygienic conditions in the baby's environment, overcrowding, faulty nursing care, and the contact of the child with infected adults are the most important sources of danger; and it is unfortunately true that despite anxious efforts by the medical staffs and lay committees of maternity institutions to reduce these risks in the nurseries and wards of their hospitals the babies born in many institutions are seriously threatened. Most of our maternity hospitals were built at a time when it was the custom to house the babies in large nurseries, where the danger of cross-infection is considerable; and the increased demand by mothers to have their babies in hospital has accentuated conditions of overcrowding. But probable that faulty nursing care is a greater danger than faulty architectural design. Such a statement should be interpreted as a criticism of the student nurses, who are for the most part conscientious, enthusiastic, and hard-working; indeed, our sympathy goes out to them in their daily struggle to achieve the impossible. Insufficient in numbers, harassed by examinations which stress theoretical book knowledge rather than practical proficiency, and sometimes irritated by rules and regulations long outdated, these women are driven to adopt a nursery technique which places a premium upon speed. The Report states that the preventive measure of greatest importance in dealing with neonatal infection is the routine observance of an orderly and unhurried basic nursing technique by a staff adequate in number and quality; and it recommends that a ratio of two nurses to three cots should be aimed at as a minimum in the nurseries. In the larger maternity hospitals and units there should be a basic permanent staff of trained nurses,

especially in the units for premature infants, sick infants, and infected infants, and there should be a trained nurse always on duty and an experienced sister, or sisters, in charge. At least one-third of the nursery staff should consist of permanent trained personnel, the remainder being trainees. These recommendations are in general agreement with those put forward by a subcommittee of the British Paediatric Association on neonatal mortality and on arrangements for newly born babies in maternity hospitals.² During the present shortage of nurses it is suggested that nursery nurses be recruited, where possible, as helpers in the nurseries, with appropriate scales of remuneration. Useful suggestions are made regarding the training of midwives, and Appendix 2 provides a detailed description of nursery technique as practised in the Aberdeen Maternity Hospital. It is interesting to compare this Appendix with the technique adopted by Beryl Corner.³ A suggestion likely to meet with the approval of paediatricians is that part of the training of a sick children's nurse might be obtained in the nursery of a maternity hospital or unit for a period of, say, three months. In regard to architecture, the Report recommends that large nurseries should be replaced by a suite of smaller wards, preferably containing from four to six cots each. Special provision is needed for (a) sick infants (10 cots per 100 maternity beds); (b) premature infants born in the hospital or admitted from the district (10 cots per 100 maternity beds); and (c) the isolation of infants suffering from infective conditions (5 to 10 cots per 100 maternity beds). Some of these special wards should be capable of holding 4 cots each, and some should be single cubicles. It may be questioned whether the Report goes far enough in this section, and a strong case can be made by those who hold that mothers should have their babies beside them: when this is done "with simple precautions not only is the danger of neonatal infection less than it otherwise would be, but breast feeding and the relationship between mother and child are firmly and safely established in a physiologically natural manner."⁴

The most dangerous of the commoner types of neonatal infection are pneumonia and epidemic diarrhoea; but even "minor" infections such as conjunctivitis, septic spots on the skin, and the common cold are liable to develop into more serious infections, and are a source of danger to other infants. The pathologists of the two maternity hospitals mentioned in the Report considered that at least 30.7% and 16.1% of the total neonatal deaths in their hospitals were due to infection. These conclusions are in line with an earlier report by J. N. Cruickshank,⁵ who in a survey of 800 neonatal deaths in a maternity hospital found that 29.75% were caused by infection. Premature infants, and those who suffer an injury at birth or neonatal asphyxia, are especially liable to fall victims, and the infection may then be a terminal complication. The clinical recognition of some types of neonatal infection presents difficulties, which probably accounted for the fact that in the two series of cases

² *Arch. Dis. Childh.*, 1943, 18, 62, 159.

³ *Proc. roy. Soc. Med.*, 1946, 39, 383.

⁴ *Spence, J. C., British Medical Journal*, 1947, 1, 125.

⁵ *Med. Res. Cncl. Sp. Rep. Ser.*, No. 145, 1930, London.

mentioned above the diagnosis was made during life in only 16.1% and 17.6%, respectively. There is, however, a general feeling among paediatricians that the higher figure is a more accurate estimate of the prevalence of neonatal infection in institutions.

Other subjects which receive consideration are the importance of breast feeding; the value of mothercraft instruction, and of better co-operation between hospital, health visitor, and family doctor; the paediatric staffing of maternity hospitals; record keeping and annual reports; the milk kitchen; and the prevention of infection when artificial feeding is essential.

SURGERY OF THE GALL-BLADDER

It is a salutary if somewhat humiliating thought that in spite of the advancement of surgery the gall-bladder continues to present many unsolved problems. Thanks to a combination of more accurate diagnostic methods, more detailed planning of pre-operative treatment, improved technique, and the development of preventive measures against post-operative complications, the mortality of gall-bladder operations has fallen in a period of 20 years from about 4% to 1% or less. Nevertheless, there is still no agreement on whether a gall-bladder should be removed from the fundus downwards—as recommended by such a sound and experienced surgeon as Allen,¹ of Boston—or from the ducts upwards. The latter method is that usually taught in this country—the former probably the more commonly practised. On page 11 of this issue Love describes a refinement of cholecystectomy based on the partial removal of the gall-bladder, combined with electrocoagulation of the residual strip left on the liver bed, which he terms diathermy dissection. This procedure allows the raw area of the liver bed to be covered either directly by peritoneal flaps or by a pad of omentum or falciform ligament. If this effects, as is claimed, sufficient sealing of blood and bile vessels to prevent post-operative drainage there is no doubt the consequent avoidance of chest complications would render cholecystectomy a safer procedure.

The author's account in the same article of an abnormal duct from the gall-bladder to the liver draws attention to the well-known multiplicity of variations in the anatomical arrangement of the bile ducts and accompanying vessels, which, combined with difficulty of access, makes the more mechanical side of gall-bladder surgery so difficult. The recent spate of articles on repair of damaged bile ducts is unfortunately not all the result of war injuries. Here again the many ingenious methods of anastomosis described show that no general agreement prevails. Another important practical consideration arises from Love's article: should the common bile duct be opened as a routine during cholecystectomy or not? The pendulum appears to be swinging towards a more conservative approach to this problem, and most surgeons would probably consider a routine cholechohogram during operation an unnecessary procedure.

Battles are still being fought over the aetiology of cholelithiasis. The advocates of stasis and infection have recently met a doughty opponent in Robertson,² of the Mayo Clinic, who has produced a convincingly argued hormonal (sex-hormone) theory for gallstone formation. The contribution from Majoor and Suren on page 8 of this issue exhibits another aspect of this evergreen subject and may throw light on it. These Dutch workers, collecting their information during the difficult days of the

"occupation," draw their interesting deductions from their post-gastrectomy cases, in some of which gallstones have developed within six months to three years after operation. Their surmise that the interruption of normal duodenal flow leads to such changes in biliary physiology that cholesterol is precipitated in abnormal quantities has both practical and theoretical significance. The biliary apparatus and its contents—physiological and pathological—still offer a wide field for research.

ANTISEPTIC TREATMENT

It is a source of enduring wonder to anyone who has followed the development of bacterial chemotherapy in the past fifteen years that the major forms of septic infection can now be treated more successfully than the minor. In the presence of a spreading cellulitis or septicaemia the indications for treatment are clear, and the results almost uniformly good. On the other hand, local septic infection, whether in a wound or elsewhere, cannot be overcome with anything like the same facility by the same or any other means. There are several reasons for this, among them the frequent presence of penicillin-resistant types of bacteria, such as Gram-negative bacilli, the relative inactivity of sulphonamides in wound exudates, and the relative inactivity of the bacteria themselves, their susceptibility to either of these agents being greatest only during active multiplication. Used intelligently, and only in the presence of susceptible infection, penicillin is of course an ideal antiseptic, but it is by no means applicable to every case, and the search continues for some other agent which will fill the gap left by its deficiencies.

A very considerable variety of antiseptics is still being experimented with, and to judge by the present literature on the subject the field is as open as it was fifteen years ago, though there is now a much firmer conviction that such treatment, properly applied, can be effective. Most of this literature is American, and it deals with almost every conceivable type of substance except the acridines. It is not easy to understand why workers in the U.S.A. disregard proflavine and the newer compounds such as 5-aminoacridine, the use of which for combating sepsis has received strong support from sources in Great Britain, the British Army, and Australia. It would be interesting if the mixture¹ or compound² of proflavine and sulphathiazole which has found favour here were included in some of the trials now proceeding in the U.S.A. An example of this type of work is that described by E. L. Howes,³ who submitted various antiseptics first to tests for toxicity, which included addition to tissue cultures, application to the eye, intramuscular and intraperitoneal injection, and observations on effect on wound healing. Zephiran, parachlorophenol, and tyrothricin were eliminated from further trials as being too toxic. The substances surviving this stage were penicillin, streptomycin, and "sulfamilon" (better known as "marfanil"). These were submitted to tests of bactericidal activity and finally to clinical trial for wound treatment.

The technique employed for testing bactericidal activity in the presence of blood was the application of the antiseptic solution on a piece of filter paper for ten minutes to a heavily inoculated blood agar plate previously incubated for three hours. This method is open to criticism, because its results do not reflect capacity to kill various species of bacteria within ten minutes, as the author appears to suggest, but rather diffusibility into the medium and subsequent bacteriostatic action. As judged in this way

¹ *Ann. Surg.*, 1945, 121, 412.

² *Surg. Gynec. Obstet.*, 1945, 80, 1.

¹ McIntosh, J., and Selbie, F. R., *Lancet*, 1944, 1, 591.

² McIntosh, J., Robinson, R. H. M., and Selbie, F. R., *ibid.*, 1945, 2, 97.

³ *Surg. Gynec. Obstet.*, 1946, 83, 1.

penicillin failed against Gram-negative bacilli and streptomycin against streptococci, but "sulfamylon" inhibited all species of organisms tested. The upshot of all these tests, together with some clinical trials, was to place "sulfamylon" first in order of merit, streptomycin second, and penicillin third, with a recommendation that the first two be used in combination.

Tyrothricin is the subject of an extensive clinical study by D. D. Kozoll and others,⁴ who illustrate the effects of applying it as a wet dressing to septic wounds: some of these were conveniently bilateral, one side being treated and the other used as a control. The results in coccal infections were good; the growth of diphtheroids and *Ps. pyocyanea* appeared to be "encouraged." E. A. Brown and his colleagues⁵ introduce a solution of carbamide peroxide in glycerine, which they propose to call "thenardol" after J. L. Thénard, the discoverer of hydrogen peroxide, as an antiseptic for various types of local infection. The main evidence presented in this paper comprises tests by the agar cup technique, a proceeding which does not in itself carry conviction even of potential *in vivo* activity, but favourable clinical results are also briefly mentioned.

POLLEN ALLERGY

Reports of air-borne allergens causing dermatitis have appeared from time to time since 1918.⁶ Such allergens may give rise to a contact dermatitis or, if inhaled, to an atopic dermatitis. Pollens are especially suitable for investigation as possible causes, since they are potent allergens and the times of their seasonal occurrences are known. Rowe in 1937⁷ presented statistical data on 30 cases of allergic (atopic) dermatitis in which inhalant allergy was the chief or only cause, pollens being the dominant influence in 27. More recently Rowe⁸ has described for the first time 6 cases of atopic dermatitis (eczema) of the hands as the sole or major manifestation of inhalant pollen allergy. He found 16 such cases out of 180 of atopic dermatitis of the hands that he has studied during the last eight years. The rash usually occurs on the backs of the hands and on the backs and sides of the fingers, less often on the palms and round the wrists. It is usually bilateral and fairly symmetrical. Often after the dermatitis of the hands has recurred for several years other areas of the skin—the face, the neck, the extremities, and very occasionally the body—may become involved. Rowe points out that, in all cases of clinical allergy, the only evidence of sensitivity may be that obtained from the history, the onset or aggravation of the rash during the pollen season being especially suggestive. The skin tests may or may not be positive; treatment confirms or disproves the diagnosis. Other causes such as other inhalants, drugs, and foods must be excluded, as must the so-called "id" reactions and especially contact dermatitis.

The treatment is perennial desensitization with minute doses of all the pollens encountered during the months when the dermatitis persists, usually using 20 to 50 types. Since the skin tests do not indicate which pollens are the cause of the eczema, all the possible causative pollens are included in the desensitizing solution in order to be certain of including the offending ones. The initial dose is 0.1 ml. of an extract varying in dilution from 1:5,000,000 to 1:5,000,000,000. Injections are given every one to three days. An increase of the itching and dermatitis usually indicates an excessive dose, while with proper dosage there

is a decrease of the rash and the itching in two to three weeks. When there is a distinct improvement the dose can be gradually increased, especially after the pollen in the air has decreased. The dermatitis of the hands in the cases recorded had existed from 3 to 18 years, with an average of 9.3 years. Satisfactory results were obtained in all 6 cases. Rowe appears not to have used inhalation to test any of his patients, and we wonder whether this might not have given a clearer indication of sensitivity than the skin tests. However, his studies are of considerable interest in this most difficult field, and his previous contributions to clinical allergy are such that his views merit the most careful consideration.

SUNFLOWER-SEED PROTEIN

The sunflower, though grown in this country mainly for decorative purposes, is in many parts of the world a valuable source of food. The seeds are rich in oil, which is edible and readily extracted. The residual meal contains up to 50% of proteins, and should therefore be a valuable food for livestock if its constituent amino-acids are such as to endow it with a high biological value. Doubts on this point were recently expressed by Day and Levin,¹ who concluded that sunflower meal is more important as a source of the vitamin B complex than of protein. In support of this view the biological value of the protein was found by Mitchell, Hamilton, and Beadles² to be inferior to that of the soya bean, and in the same low class as that of oats, wheat, and barley. Block and Bolling, however, agreed with Grau and Almquist⁴ in claiming that the amino-acid analysis of the meal compares very favourably with that of beef muscle. Which of these conflicting views was to be believed? Experiments to clear up this point have now been reported by Grau and Almquist.⁵ In this work the growth rates of chicks given South American sunflower meal as a source of protein were compared with the rates of others given casein or sardin meal. As a result the sunflower meal was found to be fully equal to these excellent sources of protein. Its biological value, moreover, was not improved by adding lysine—an amino-acid which is deficient in many cereal and oil-seed proteins. When given at a level equivalent to 20% of protein in the diet the sunflower meal was satisfactory as a complete source of amino-acids for the young chick.

If these results are duly confirmed the sunflower must rank high in nutritive value, particularly among vegetable foodstuffs. In a practical way its excellence has already been recognized in Soviet Russia and other parts of the world, where it is grown in large quantities. In our own country, however, its value as a possible alternative to more familiar crops must obviously depend not only on the food value per unit weight of seed but on numerous other factors, including the yield of seed per acre. Whether sunflowers deserve more attention than that already given by the backyard poultry-keeper, and could profitably take the place of other crops in well-tilled soil, is a question which only the expert agriculturist can decide. A plant which yields both oil and good quality protein, and which does not require tropical warmth or moisture for its cultivation, is, however, certainly worth intensive investigation. The plant-breeder should inquire into the possibility of evolving improved strains with larger seeds and higher oil content. The colonial administrator should not neglect the possibilities of the sunflower when faced with unpromising soil which is unsuitable for other crops.

THE FOUNDLING HOSPITAL CHILD WELFARE SCHEME

BY

D. H. GEFFEN, M.D., D.P.H.

M.O.H., Metropolitan Borough of St. Pancras

In the early part of the 18th century a certain Capt. Thomas Coram travelled the seas in the Merchant Navy, and during his voyages he was so shocked at the sight of the deplorable conditions under which children were living that he determined when he retired to do something to better their lot in his own country. In 1739 he found the means to achieve his purpose and in 1741 he rented a house in Hutton Gardens for destitute children. In 1745 he completed the building of the Foundling Hospital in Brunswick Square. Hogarth was one of the earliest governors and Handel was also a benefactor. Many will remember this building, which was pulled down within the last few years. It had charm of design and was one of the remaining features of early 18th century London. It was not, however, entirely suitable for the care of children. In 1926 the governors sold the site and buildings and moved temporarily to Redhill, later finding their permanent home at Berkhamsted.

Much controversy ensued on the future of the Brunswick Square site, and at one time it appeared as though St. Pancras would lose this open space, which would be utilized for building purposes. It was largely due to the efforts of Mrs. G. M. Trevelyan that nine acres of the area were made available as playing fields, and the governors were able to repurchase 100,000 sq. ft., to be known as Coram's Gardens, which they determined to use for the benefit of young children. They erected a residential nursery and a day nursery (see Fig.) for

children of the neighbourhood as a memorial to Capt. Coram on the site where he built the original Foundling Hospital, and together with these a model nursery school for some 80 children with a series of large rooms for the instruction of pupils in the care of babies and children. All the arrangements for the residential and day nurseries and the nursery school are ideal, providing ample playing space, a southern aspect, hygienic walls and floors, the most modern toilet arrangements particularly suited to young children, and window space of ideal proportions in a building of beautiful design.

When all these preparations were completed the war broke out in 1939, and it was decided that London was unsuitable for keeping a large number of children together in an area likely to be attacked by enemy action. The premises were requisitioned by the St. Pancras Borough Council and used as a rest centre, in which capacity they were of inestimable value. A year or two later, however, the need for day nurseries in London became of paramount importance to enable women to work. By arrangement with the governors the ground floor of the residential nursery was utilized by the St. Pancras Borough Council as a wartime day nursery, and the governors made available to the Council their furniture and equipment. At the end of the war it was possible to derequisition that part of the premises used as a rest centre, and in due course the nursery school block was opened and is now administered by the St. Leonard's Nursery School Committee with the help and support of the governors.

The next development was the need to find residential accommodation for babies, and by arrangement with the St. Pancras Borough Council the first floor of the day nursery has been made available for this purpose. A scheme has been agreed between the governors of the Foundling Hospital and the St. Pancras Borough Council whereby there shall be one matron, one doctor, and one kitchen staff for both the day and the residential nurseries, but the nursing staff will be separate. It

is hoped that within a matter of weeks the residential nursery will be open and receiving its first young residents. There will then be on the site a day nursery, a residential nursery, a nursery school, and teaching quarters ideal in design and efficiency.

Teaching Centre

It became obvious that here was not only an opportunity for caring for young children by the many means now considered appropriate, but an excellent opportunity for teaching, for over the road is the Great Ormond Street Hospital for Sick Children with the Nuffield Institute of Child Health, and nearby is the London School of Hygiene and Tropical Medicine, both bodies keenly interested in teaching child welfare to doctors from both Britain and the Empire. The friendly help of Col. Nichols, secretary of the Foundling Hospital, made it easy for Prof. Alan Moncrieff, as Director, and for me, as lecturer on Public Health at the Institute of Child Health, to place a plan before the governors to complete their scheme for the care of children.

We suggested that the war-damaged building originally used as a canteen and later as a laundry should be repaired and converted to form a maternity and child welfare centre, with ultimate provision for a minor ailment clinic for school-children. A tentative ground plan was prepared by the architect. At this stage the governors are prepared to carry out the work to convert this derelict building into a maternity and child welfare centre provided the local authority will be responsible for its maintenance, staffing, and upkeep.

The governors of the Foundling Hospital placed this proposition before the St. Pancras Borough Council, and it received their immediate and whole-hearted support. The scheme links the governors' welfare work on the Foundling site with local authority activities and co-ordinates it with the Institute of Child Health at Great Ormond Street Hospital. It is anticipated that the staffing of the welfare clinic, and possibly even of the residential nursery, may in due course be carried out in conjunction with that hospital. In addition, this site would provide a training ground for postgraduate teaching at the Institute of Child Health for doctors studying for the Diploma in Child Health and for nurses as well. Co-operation already exists between the Institute and the St. Pancras Borough Council, for the medical officer of health of St. Pancras is lecturer at the Institute, the assistant medical officers of the Council are external tutors, and there is interchange of staff between the Institute and the Council's welfare medical officers—a scheme suggested in the report of the British Paediatric Association. This proposal to build a welfare centre will be placed before the Ministry of Health for approval and will be considered by them in conjunction with the L.C.C., which is the new health authority and will be responsible for child welfare in the near future.

Associated with the child welfare activities of the governors on this site there exist the residential schools at Berkhamsted and homes which they are administering for the care of women and children. Furthermore, a large area adjoining the site has been scheduled for the erection of one of the L.C.C.'s new schools, and the St. Pancras Borough Council has acquired many acres on which it has already begun to build blocks of modern flats. If this scheme is adopted there will be on this site and in the vicinity modern flats, a modern school, a nursery school, a residential nursery, a day nursery, a maternity and child welfare centre, a school clinic (possibly with a dental clinic), a swimming pool, nine acres of playing fields, and perhaps one of the clinics envisaged in the new Act for general practitioners—and this in the heart of London and in the centre of London's teaching district. It will indeed be a centre of health and health teaching, and an example of the finest type of co-operation between the Government, local authorities, teaching bodies, and voluntary associations.

The Board of Registration of Medical Auxiliaries has recently published the seventh edition of its *National Register of Medical Auxiliary Services*, which gives the names and addresses of persons engaged in work ancillary to medical science and practice. Medical practitioners may obtain a copy free from the Registrar, Board of Registration of Medical Auxiliaries, Tavistock House North, Tavistock Square, London, W.C.1.

BARTHOLOMEW MOSSE

FOUNDER OF THE ROTUNDA HOSPITAL

Next week the Rotunda Hospital is celebrating its bicentenary. An International Congress of Obstetricians and Gynaecologists will discuss such subjects as puerperal sepsis, eclampsia, and obstetric shock. There will be receptions, dinners, and sherry parties. Ireland always does these things well, and Dublin outstandingly so. According to Oliver St. John Gogarty, Dublin is "a state of mind," but it is a state of mind best appreciated within easy reach of O'Connell Street.

In the course of the celebrations, which the war prevented being held in 1945, the Congress will hear addresses by Mahfouz Pasha, from Egypt; Prof. Bernhard Zondek, from the Hadassah Hospital in Jerusalem; and many distinguished guests from the U.S.A., France, Belgium, Scandinavia, India, South Africa, Australia, Canada, and Great Britain. These and other notable visitors will in their turn be sure to hear some mention of Bartholomew Mosse. They will see his bust in the front hall of the Rotunda Hospital and the portrait which hangs in the board room. There is also an engraving, here reproduced, which he signed and which is in the possession of the Royal College of Physicians of Ireland.

Curran (1945) says that "Dr. Mosse was a man of quite unusual initiative," and that he showed "a magnificent recklessness . . . in the way he risked his reputation and personal fortune in his philanthropic venture." O'Donel Browne (1947), whose recent book is reviewed elsewhere in this issue (p. 17), pays tribute to "his dauntless courage and clear vision." Kirkpatrick in his book, and more recently (1945), has described how Mosse "boldly embarked on his great design." These three authors have told, from different points of view, the history of the Rotunda Hospital.

For the first full account of its remarkable founder it is necessary to go back to an unsigned article published in the *Dublin Quarterly Journal of Medical Science* at the time of the hospital's centenary. Its opening sentences could not, and should not, be paraphrased.

"Men will labour diligently for their own advancement, either directly or indirectly, and will even contribute liberally to the relief of distress; but how seldom do we see an individual devoting his time, his talents, bodily and mental labour, and his wealth, to the sole purpose of raising up an asylum for the relief of suffering, and, at the same time, for the improvement of his own profession, without the prospect—nay, we may say, without the possibility—of an adequate reward? And yet this was what was done, simply and without display, and, as will appear by the following memoir, under circumstances of unparalleled difficulty, by the founder and builder of the Lying-in Hospital in this city."

Early Days

The Rev. Thomas Mosse, rector of Maryborough, Queen's County, gave his son, Bartholomew, who was born in 1712, a "genteel education." The young man was then apprenticed to John Stone, a Dublin surgeon. By the time he was 21 Bartholomew Mosse was said by the Surgeon-General to be "very well qualified to practise the art of surgery." For a while he had medical charge of men "drafted from Ireland to complete the regiments in Minorca," and later he studied midwifery in England, France, and Holland. Returning to Dublin,

he was admitted a licentiate in midwifery of the King's and Queen's College of Physicians on May 22, 1742. A year later he married his first cousin, Jane, a daughter of the Venerable Charles Whittingham, Archdeacon of Dublin. His first wife had died childless in 1734.

"In the course of his practice charity often demanded his assistance; and he hath often declared, that the misery of the poor women of the city of Dublin, at the time of their lying-in, would scarcely be conceived by any one who had not been an eye witness of their wretched circumstances; that their lodgings were generally in cold garrets open to every wind, or in damp cellars, subject to floods from excessive rains; destitute of attendance, medicines, an often of proper food, by which hundreds perished with their fruit infants.

"These distresses excited his compassion, and he resolved no longer to delay his endeavours to establish an hospital for poor lying-in women. Having communicated this humane and charitable

intention to a few particular friends who highly approved of his scheme he took a large house in George Lane, which he furnished with bed and other necessities, and opened the same on the 15th of March 1745, continuing to support chiefly at his own expense, and constantly attending it in person until the apparent usefulness of induced several well-disposed persons to encourage the undertaking by benefactions and yearly subscriptions, which encouraged him to enlarge his plan."

It was obvious that any enlargement would cost a great deal of money. Mosse proceeded to raise the money by "plays, lottery schemes, concert oratorios, etc.;" and we mention that he brought over Castrucci, the last pupil of Corelli, as an attraction to the concerts." It should perhaps also be mentioned that the first play arranged by Mosse for the benefit of the Lying-in Hospital was *The Conscious Lovers*. In August, 1748, he had a lease of £70 a year of the present site and a plan for a new hospital. The original Dublin Lying-in Hospital for Poor Women in existence had dealt with 3,900 deliveries at a total cost

Bartholomew Mosse

£3,913 13s. The maternal death rate was slightly more than 1%, the stillbirth rate 1 in 34, and the neonatal death rate 1 in 17. On the new site "he first, at the risk of his whole fortune, laid out and furnished a garden, with an orchard, coffee-room, and decorations, for the entertainment of the public in the manner of Vauxhall, near London, whereon he expended about £2,000. He then employed a band of music and soon found his expectations fulfilled by a constant resort of company during the summer season which produced near £400 annually."

The New Hospital

The foundation-stone of the new hospital was laid by the Lord Mayor of Dublin on June 4, 1751. At this time, in his own words, Mosse was "barely worth £500" and well aware that the hospital would cost £20,000. So he promoted a lottery and sold many tickets, but "the Lords Justices would not allow the drawing." He went to London with a similar project in mind, and "his enemies raised many scandalous and fresh reports giving out that he had absconded for debt and could never return." Another lottery caused further difficulties and ended in his arrest at Holyhead. Nothing daunted, Mosse escaped through a window, persuaded two boatmen to take him some distance away, and "remained in a poor cabin on the wild mountains of Wales for some weeks before he would venture home."

Despite these and other difficulties the building of the new hospital proceeded. Though not completed, it was opened on Dec. 8, 1757, and immediately admitted "fifty-two poor women, great with child, who attended in the hall with proper certificates for admission, and were all decently clothed in uniform at the expense of the hospital, each in a blue calimanco gown and petticoat, shift, handkerchief, cap, and apron." The Round Room, whose name has gradually passed to the hospital itself, had yet to be built, but Mosse was a sick man.

"Having greatly impaired his health by intense study and application of mind, by his close attention to the business of the hospital, by constantly superintending the building, and by several fatiguing journeys to London, to forward his schemes, he did not long enjoy the pleasure arising from the success of his labours, for he grew so ill in the beginning of the winter of 1758, that he was obliged for the most part to confine himself to his chamber. Several physicians attended him, but, finding all their endeavours ineffectual, they advised him to return into the country. On this occasion Alderman Peter Barre made him the kind offer of his house at Cullenswood (about a mile from town), which the Doctor readily accepted; and there, on the 16th of February following, he departed this life in the 47th year of his age, and was interred at Donnybrook, leaving the new hospital a monument to posterity of his surprising perseverance, diligence, and ingenuity, and indeed one of the most superb architectural ornaments of the great and elegant city of Dublin."

Bartholomew Mosse was followed as Master by Fielding Ould. In a brief lifetime he succeeded in accomplishing what he set out to accomplish.

We are indebted to the Royal College of Physicians of Ireland for permission to reproduce the engraving of Bartholomew Mosse

SEPTCENTENARY OF BETHLEM

Bethlem mental hospital, which was discussed in these columns last week (June 28, p. 935), celebrated the 700th anniversary of its foundation on June 28. A commemoration service was held in the Lady Wakefield Chapel, conducted by the Bishop of Croydon and attended by the Lord Mayor of London as senior governor. The association of Bethlem with the City of London was further emphasized at a luncheon when the principal speech was made by Mr. Ralph Assheton, Member of Parliament for the City, who, recalling the fact that Bethlem began its existence in the reign of Henry III as a monastery, said that formerly the physician of the soul and the physician of the body were often one and the same person, and suggested that the separation of these functions which modern science had brought about was in many respects unfortunate. Sir Arthur Rucker, deputy secretary of the Ministry of Health, responded for the guests. Later in the afternoon a garden party in the grounds of the hospital was attended by H.M. Queen Mary, who planted a tree to mark the occasion. Demonstrations were given in the occupational therapy department and in the Lord Wakefield treatment and research unit. The visitors included many psychiatrists from various parts of the country.

CLINICAL TRIALS OF STREPTOMYCIN

Doctors in southern England, including the London area, wishing to propose cases of acute military tuberculosis or tuberculous meningitis for admission to a Medical Research Council trials centre for streptomycin treatment should, from July 4, make their request through the Emergency Bed Service, London (Monarch 8515: day and night service). The Service will be kept fully informed of the number and type of cases which can be admitted to each centre, and where a bed is available will direct the inquiry to the appropriate medical officer. It should be emphasized that the number of cases which it will be possible to admit for treatment during the period of the present tests is still limited. Trials of streptomycin in tuberculous meningitis in children aged up to 8 are also being made, under the Council's authority, at the Alder Hey Children's Hospital, Liverpool, and the Royal Hospital for Sick Children, Glasgow, as was indicated in a recent annotation (June 7, p. 814).

DR. ANGELUS

A NEW PLAY BY JAMES BRIDIE

The work of a medical playwright always holds a special interest for his colleagues. James Bridie's new play, *Dr. Angelus*, was given its first performance in Edinburgh last week. Ranging over the medical curriculum, Bridie has shown us the romance of the dissecting-room in *The Anatomist* and, while the clergyman slept, has drawn in heroic lines the drama of the laboratory and tilted at some theories of eugenics. *Dr. Angelus* takes us through the medium of the far-from-chromium-plated consulting-room of a Glasgow general practitioner (of Edinburgh training) into the realms of psychopathology. This eccentric gentleman successfully murders his mother-in-law and his wife on the entirely logical grounds that women of their mediocre intellectual and other qualities are a handicap to the full development of his capacities and are at the same time insured for useful sums of money. This he accomplishes by the simple expedient of persuading them that they are ill and "treating" them with spectacular doses of antimony. As part of the "build-up" designed to prevent any unenlightened interference with his plan he takes into partnership an earnest and simple-minded young Englishman, a product of Durham University and St. Thomas's Hospital, and cajoles him into signing the death certificates. As a further precaution he calls in, at a last-minute consultation, Sir Gregory Butt, whom he endeavours to deceive with details of careful clinical investigation and an appearance of affectionate solicitude, albeit perfunctorily and contemptuously, since he shrewdly guesses that worldly considerations will ensure that Sir Gregory will take none but evasive action in the face of a very fishy and unsavoury business. In the end his schemes suffer the frequent fate of those of mice and other men. Fate steps in, taking the shape of the Glasgow C.I.D. and a lady patient, who conceives a dislike for Dr. Angelus and an affection for the young doctor, largely because he recites the Hippocratic Oath to her at the psychological moment. Mrs. Corcoran, the patient, happens most inconveniently to be the wife of an insurance agent.

These contrivances provide full scope for the familiar pawky satire. The poor young Sassenach, Dr. Johnson, barely misses an abrupt and early termination to his career by innocently telling Sir Gregory Butt that his experience in Glasgow has not impressed him with "provincial medicine." The pompous, sanctimonious humbug that is the outward sign of the Angelus megalomania provides a whole rack of pegs on which to hang verbose latinity. The mother-in-law is not "dying" but "hovering on the brink of dissolution." The acting of every one of the small cast of eight is of a high order. Mr. Alistair Sim, one fancies, may well have been in the author's mind when he wrote the play. The appearance, gestures, and diction which gave such a fascinating twist to the parts of the detective in the film *Green for Danger* and the author in *Hue and Cry* are turned to good account in portraying the unctuous insincerity of Dr. Angelus. The one really dramatic incident in the play occurs almost at its end when Angelus is trapped and arrested, and Mr. Sim rose to it magnificently. The dawning realization by the maniac that the whole concept of a super-intelligence mastering Fate was but an illusion, finally shattered by a pair of handcuffs, is brilliantly acted. It reflects in no way on the other members of the cast to mention the admirable performance of Mr. George Cole as young Dr. Johnson and that of Mr. Archie Duncan in the smaller part of the police inspector, more representative perhaps of Scotland than of Scotland Yard.

The play, which is first-class entertainment, is described in the programme as a "psychological thriller." How the author regards it is not easy to guess from his whimsical reference to it in a first-night speech as "this wholesome little play." One suspects parody. However that may be, its main appeal is cerebral and not thalamic, and those who go expecting flesh-creeping thrills will be disappointed. The doctor who sees it will appreciate the professional touch in the clever and subtle picture of a psychopathic type and the not too unkindly flits at the foibles he often notes in his colleagues.

Nova et Vetera

PAEDIATRICS FOUR HUNDRED YEARS AGO

Those who have followed the latest development and plans in paediatrics and child health may find it enlightening to study a work on children's diseases first published in 1545. It is *The Regiment of life, whereunto is added a treatise of the pestilence, with the Booke of children*, by Thomas Phaier. Like Shakespeare's, the name has several variations. Sir Frederic Still in his *History of Paediatrics* gives the following: Phaer, Phayer, Phayre, etc. The volume from which these extracts are taken is a later edition which is in the medical library of Bristol University. It is stated on the title page to be, "newly corrected and enlarged," and was "Imprinted at London, by Ihon Kyngston and Henry Sutton, dwelling in Paules Church-yard. Anno Domini 1553." It is the first work on paediatrics written by an Englishman, and one of the first medical books to be published in English. The author finds it necessary to apologize for not using Latin:

"But my purpose is here to doo them good that have most neede, that is to saye children: and to shewe the remedies that God hath created for the use of man, to distribute in englyshe to them that are unlearned parte of the treasure that is in other languages, to provoke the [them] that are of better learning, to utter their knowledge in suche lyke attempts: fynally to declare that to the use of many, whyche oughte not to be secrete for lucre of a fewe.

I intend in this boke . . . to treate only of the thyngs necessary, as to remove the sicknesses, wherewith the tender babes are oftentimes afflicted, and desolate of remedye, for so much as many do suppose that there is no cure to be ministred unto the by reason of their weakenes. And by yr [their] wayne opinion, yea rather by a foolish feare, they forsake many that myght be well recovered, as it shall appeare by the grace of God hereafter in this lytl treatyse, when we come to the declaration of the medicines."

Phaier strongly advocates breast-feeding, not only on his own account but also as a part of traditional wisdom.

"The Poet Virgyl . . . being thoroughly expert in the priuities of nature understode right wel how great an alteracion everyting taketh of the humoure by whiche it hath his alymente and nourishing in the youthe: whiche thing also was considered and alleged of many wyse Philosophers: Plato, Thophrastus, Xenophon, Aristotle, and Plinie, who did al ascribe unto the nourcement as muche effect or more, as to the generation. . . .

Wherefore as it is agreeing to nature, so is it also necessary and comly for the own mother to nource the owne child. Whiche if it maye be done, it shall be moste commendable and hoisome, if not ye must be well advised in takyng of a nource, not of ill complexion and of worse maners: but suche as shalbe sobre, honeste and chaste, well fourmed, amiable and chearefull, so that she may accustome the infant unto mirth, no dronkarde, vicious nor fluttyshc, for suche corrupteth the nature of the chylde."

His "Remedies appropriate to the encreasing of milke in brestes" are very much like the formulae of some of the modern proprietary lactagogues:

"Parsneppe rotes, and fenelle rotes, sodden in broth of chickens, & afterwarde eaten with a little fresh butter." Or, "The poudre of earth wormes dried and dronken in the brothe of a neates tongue." "These thynges have propertie to augment the milke, dylle, anyse seede, fenelle, cristal, hore-hounde, fresh chese, hony, lettuse, beetes, myntes, carette rotes, parsneppe, the dugges or udder of a cowe or a shepe, goates milke, blaunched almondes, ryce porrage, a coves toungue dried and made in poudre, potched egges, saffron, and the uice of roasted yeale dronken."

The list of diseases mentioned is fairly comprehensive:

Apostumes of the brayne, Swellyng of the head, Scalles of the head, Watchyng out of measure, Terrible dreames and feare in the slepe, the falling evyll called in the greke tonge epilepsy, the Palsey or shakyng of members, the Crampe or spasmus, Styfnesse of limmes, Bloud-shotten eyes, Wateryng eyes, Scabbynesse and yche, Disease in the eares, Neasing out of measure, Bredyng of teeth, Canker in the mouth, Quinsie, or swellenge of the throte, Cough, Streynesse of wynde, Feblenesse of the stomake and vomiting, Yeaxing or hicket, Colyke and rumbling in the guttes, Fluxe of the belly, Stopping of the belly, Wormes, Swellyng of the navill, the Stone, Pyssyng in bedde, Brustyng, Fallyng of the fundament, Chafyng of the skynne, Smal pockes and measilles, Feuers, Swellyng of the coddess, Sacer ignis or chingles, Burnyng and scaldyng, Kybbes, Consumption, Leanenesse, Gogle eyes.

Many of his descriptions reveal a keen observation, for instance:

"Of Wormes. There be divers kinds of wormes in the belly, as long, short, round, flat, and some small as lice. . . . In the long & rouid the paciēt commonly hath a drie cough, paine in the belly and about ye guttes, somtyme yeaxing [hiccough], and trembling in ye nighte, & starte sodainly and fal aslepe agayne, other whiles they gnasshe and grynd their teeth together, the eies waxe hollowe with an eygre loke, & have great delyte in slombring and silence, very loth when they are awaked. . . . Many have but small desyre to meate, and when they desyre they eate very gredelye . . . the hole body cōsumeth and waxeth lcanne the face pale or blew: somtyme a fluxe, sometimes vomite and in some the bellye is swollen as stiffe as a taberet.

The long and brode wormes are known by the signs that is to say yellownesse or whittishnesse of the eyes, intollerable hunger, great gnawynge and grypyng in the belly, specially after meate, water commyng out at the mouth, or at the fundament, continuall yche and rubbing at the nosethrilles, sonken eies and a stinkyng breath, also when the person doth his easement there appeareth in the donge litle flat substances muche like the seedes of cucumers or gourdes.

The other lesser sorte are engendred in the great gutte and may well be known by the excedyng yche in the fundament within, and are oftentimes sene commyng out with the excrementes: they be called of phisicians ascarydes."

The treatments recommended are scolitabotan² or herbe coralline, gall of a bull, colocinch, aloes, and wormeseede.

Again, of Chafyng of the skynne: "In the flankes, arme-holes and under the eares, it chaunceth oftentimes that the skynne fretteth either by the chyldes owne uryne or for the defeaute of wasshyng or els by wrapping and keeping to hote." Of "Watching out of measure," or sleeplessness, Phaier says:

"Slepe is the nouryshment and foode of a sucking child, and as much requisite as ye very teate, wherefore whā it is deprived of the naturall rest, all the hole body falleth in distemper: cruditie and weakenes, it procedeth commonly by corrupcion of the mylke, or to muche abundance, whiche overladeth the stomake, and for lacke of good dygestion, vapours and fumes aryse into the head, and infect the braine, by rason wherof the child can not slepe, but turneth and vexeth it self wth crying."

The treatment which he recommends would not find favour nowadays: "If you can gette any syrupe of popye, geve it to the chylde to lick . . . also an oyntment made of seede of popy and the heades." Of Terrible dreames and feare in the slepe:

"Oftentimes it happneth that the chylde is afraid in ye slepe, & somtymes waketh sodainly, & sterreth, somtymes shrieketh and trembleth, whiche effect commeth of the arysing of stynkyng vapours out of ye stomake into the fantasie, and senses of the brayne." The prevention of this: "take hede that the chylde slepe not with a full stomake, but to beare it about wakyng, tyl part bee dygested, and whan that it is layde, not to rocke it muche for overmuch shaking letteth digestion and maketh the childe many tymes to vomite."

Other treatments are, for Brustyng (i.e., hernia), caused by "greate cryeng and stoppyng of the breath, byndyng to straighte, or by a fall or of to greate rockyng and such like . . . the guttes fall downe into the cod, which if it be not utterly incurable, may be healed after this forte. First laie the pacient so upon hys backe, that his heade maye be lower than his heeles, than take and reduce the bowles with your hande into the due place, afterwarde ye shall make a plaister to be layde upon the coddess, & bounde with a lace roun about the backe."

Fallyng of the fundament: "The gut called of the latine: rectum intestinum, falleth out at the fundament, and can not be gotten in agayne without peine and labour . . . let the child sit in a hote bath made of the decoction of mallowes holyhocke, lyneseede, and the rootes of lylyes, wherein ye shall bathe the fundament with a softe cloute or a sponge and whan the place is supplied thruste it in agayne."

Finally, for Smal pockes and Measilles, Phaier gives advice which can scarcely be bettered even now: "The best and most sure helpe in this case is not to meddle with anye kynde of medicines, but to let nature work her operacion."

H. R. E. WALLIS.

Preparations and Appliances

SAFETY APPARATUS FOR ADMINISTERING TRILENE-AND-AIR ANALGESIA

DRS. A. L. HYATT, T. H. GARDENIER, and JOHN ELAM write: trichloroethylene ("trilene"), which has proved a satisfactory anaesthetic agent in general surgery, has a special value in obstetrics for obtaining both anaesthesia and analgesia. Trilene, in therapeutic doses, is pleasant to inhale, causes little or no nausea or vomiting, does not interfere with the normal contractions of the uterus, and, so far as our experience goes, does not appear to have any harmful effect on mother or baby. Its chemical formula is somewhat akin to that of chloroform, and it is possible that "delayed chloroform poisoning" may occur after the administration of trilene, though no cases have yet been reported. Cardiac irregularities have been noticed with some frequency under full trilene anaesthesia, but not when trilene is administered to obtain analgesia in obstetrics.

Given a safe apparatus, it appears that trilene analgesia can be safely administered by the midwife. Dr. Hyatt, of Barnet, as designed such a machine, which is produced by Messrs. Eiba Gorman and Co., Davis Road, Folworth, Surrey, and which is described below.

Description of Apparatus.—Trilene is poured through the liter-cap, A, while the apparatus is held in an inverted position. Air is inspired through four air-holes, B, passes down through an outer tube, C, and then over the surface of the trilene and up another tube inside the tube C, thence to the rubber tubing and facepiece. D shows a spring ratchet; E is an expiratory valve; F shows variable air adjustment and G a locking device for extra air. H is a locking device for the bottle; J a key to fit and K, and L shows an anti-siphon device.

The special advantages associated with the new apparatus are: (1) it cannot be overfilled; (2) liquid trilene cannot reach the patient; (3) the bottle cannot be unscrewed except by using the key; (4) the midwife could not make the percentage of trilene too strong, as this is prevented by a locking device; (5) the proportion of air over trilene is always a constant factor, owing to the air inlet design, and is not altered by depth of inspiration; (6) the clamp is designed on a spring ratchet and is perfectly stable in any position; (7) a graduated scale of extra air* is calculated from 0-10 and set to an arrow.

Two of us (T. H. G. and A. L. H.) have administered trilene to 300 patients in their own homes without once failing to obtain adequate analgesia, and without the slightest harm to mother or baby. At Wellhouse Hospital, Barnet, trilene-and-air analgesia has been in use since the autumn of 1941. The number of cases receiving this form of analgesia has been limited by the necessity for training midwives in gas-and-air analgesia. Dr. Canwarden, of St. Luke's Hospital, Guildford, reports, after having two of Dr. Hyatt's machines in use at this hospital: "The patients are most enthusiastic about trilene analgesia, and I have done a matter of a dozen forceps deliveries, with the patient giving her own anaesthetic."

* This does not mean percentage of trilene to air.

Drs. Greig and Goodheart, of St. Helier Hospital, Marshallington, have kindly carried out an investigation to enable a comparison to be made between the degree of analgesia obtained from trilene and air (from the new machine) and that given from the standard Minnitt apparatus. They consider that the results obtained are not yet convincing from the obstetric angle, as the number of cases was too small. The midwives in charge noted no effect on labour contractions from trilene. Drs. Greig and Goodheart conclude: "We are very pleased, and would always elect to have a trilene machine for convenience of transport, convenience of maintenance, and cheapness; and, of course, the trilene machine scores over anything else of the kind in being capable of different concentration, especially in being capable of concentration to full anaesthesia. We want to do a lot more of these cases rather quickly."

Reports of Societies

ACUTE OTITIS MEDIA

At a meeting of the Section of Laryngology and Otology of the Royal Academy of Medicine in Ireland on May 15, the President, Dr. T. G. WILSON, welcomed Mr. GEOFFREY H. BATMAN, of St. Thomas's Hospital, London, who read a paper on "The Place of Chemotherapy and Penicillin in the Treatment of Acute Otitis Media."

He said that for years he had been sceptical of the claims made for chemotherapy, and cited cases in which mastoid operations were necessary after the otitis media had apparently been cured. He showed statistics to illustrate the difference in the results of those cases treated with the sulphonamides and penicillin and those untreated. In the sulphonamide group the incidence of mastoid operations was higher and the duration of stay in hospital longer, but there was a reduction in the number of cases with dry ears that later developed otorrhoea. He thought that sulphonamide therapy had little effect on the course of otitis media, but would frequently cause an ear to become dry even in the presence of an infected mastoid. It was therefore necessary not to pronounce a cure until the hearing had completely returned, with full lustre of the membrane. He recommended x-ray examination if response to treatment was not satisfactory after three to four days, since this would be invaluable as a control if skiagrams were later required.

Dr. T. O. GRAHAM said he was a strong supporter of the use of sulphonamides and penicillin in the prevention of complications in otitis media. In their hospitals to-day a mastoid operation was rare, due to the fact that the general practitioners were well tutored in the use of penicillin and sulphonamide and gave them adequately and early. Their very low figure of mastoid operations might possibly be due also to the fact that their organisms were less virulent, but he considered it a dangerous thing to preach that sulphonamides and penicillin should not be used in cases of otitis media.

Dr. A. FAGAN said that in his earlier days myringotomy was quite common, but since the advent of the sulphonamides and penicillin that operation had practically disappeared. However, though the advent of sulphonamide had lessened the occurrence of acute otitis media here, it should be borne in mind that this had coincided with the compulsory examination of school-children. Dr. R. R. WOODS said that the incidence of the mastoid operation had always been much higher in England than in Ireland, and suggested this might be due to different bacteria or different types of ears. Since the advent of chemotherapy the incidence of mastoid operations had diminished to about one-fifth of what they previously were. On the whole he did not think the speaker's figures comparable with those in Ireland.

Health Bulletin, issued by the Chief Medical Officer of the Department of Health for Scotland, appears for the first time in its 54 years' existence free of its confidential cover. It records an address on infantile cerebral palsy by Dr. Earl Carlson, of New York, an article on the psychosomatic aspects of chronic sickness by Dr. J. L. Halliday, a lecture on anaemia in infancy and childhood by Dr. G. B. Fleming, as well as an interesting review of influenza in Scotland.

Correspondence

General Knowledge and General Practice

SIR,—As one who has been for some time seriously concerned about the matter which Dr. D. N. Baron raises (June 21, p. 902) and has even endeavoured, in a recent book, to provide some small means to help the doctor to fill the important gaps which Dr. Baron mentions, I am glad to see the subject brought out into the open in your columns. For the successful conduct of medical practice in a living society among patients whose lives must be fitted into the social pattern it ought to be abundantly clear that the doctor must know something about the anatomy, the physiology, and the pathology of society, as well as having some conception of the manifold incidentals—the arts, the humanities, and the philosophies—which colour his patients' lives. The possession of such knowledge is one of the characteristics of the good doctor. It often distinguished the "old-fashioned" G.P. from his scientific successor, however much the latter might tend to feel superior to the former, and it may well be one of the reasons why, even nowadays, academic prowess does not always presage success in the daily work of medicine.

It is all to the good that we should wake up to the fact that the medical school, even where it is nominally part of a university, tends to isolate its students from those in other faculties. It is inevitable that those in the later stages of a six-year course should mix little with those taking a three-year course in other subjects, but even in his first preclinical years the medical student's first allegiance is usually given to the hospital in which his future lies rather than to the university or college in which he is spending his present. Where the hospital medical school contains its own pre-clinical department, so that the student not only loses the need to be associated with a university but is even robbed of contact with students who are doing biology or physiology for a B.Sc. degree, the position is obviously worse.

An important contribution to the present situation has been the custom by which the youngster takes his first M.B. before leaving school. It may be in keeping with the baser materialism of to-day to regard the two years between matriculation at 16 and university entrance at 18 as wasted unless they are used in anticipating the first university year, but it is in those years that the young man or woman could not only learn the beginnings of the arts, the humanities, and economics but could develop that interest in them which would enable him, or her, to make full use of any incidental opportunities which might turn up during the medical student years.

It might be a useful immediate remedy to insist on the last two years at school being spent in real education; most good schoolmasters would co-operate. At the same time there is every reason why throughout the medical curriculum some attention should be given to these ancillary subjects. They are, in the full sense, part of social medicine, and it is encouraging to know that one British university at least is planning to teach a little sociology to both preclinical and clinical medical students. What we must avoid is the pretence that the individual who is interested can learn this sort of thing after he qualifies. He will be too busy at the wrong hours, and there is always some little constraint and restraint which hedges in the doctor. He is separated from his fellows on the human plane by the actual or potential professional relationship which subsists between the doctor and the layman. Most of all, unless he has learnt something of the elementary grammar of humanity before he is 25, he is going to find it hard to read profitably in the book of mankind. Shaw had a phrase for us in *Man and Superman*: "Not educated—only college pass-men." Surely the doctor is the last of all men who should merit such a description.—I am, etc.,

Colchester.

JOHN D. KERSHAW.

SIR,—Is it too much to hope that the advocates of the mass production of medical practitioners—I use the designation deliberately—will ponder the letter of Dr. D. N. Baron (June 21, p. 902)? There must be a considerable number of doctors who feel as Dr. Baron does, and from time to time attention has been drawn in the *British Medical Journal* to the need for a wider general education among the entrants into the profession. I go further than Dr. Baron and maintain that, in the

case of the medical specialist even more than of the general practitioner, the first prerequisite is, in his own words, "the broad cultural background." Perhaps I may be permitted to quote from an unpublished essay which I wrote some five years ago:

"Let us pass to another aspect of the place in human affairs of biology and medicine. With the tendency to reduce all life to equations or formulae, we are apt to move along in one direction and develop one-track minds. In particular I refer to the cult of specialization which is growing. I do not decry specialization in science or medicine because for present-day civilization such specialization fills local or momentary needs; but, if I may be allowed to borrow a military expression, such specialization should be regarded merely as the 'tactics' of life, and more and more attention will need to be paid to the broader 'strategy' of life towards which we should bring a broader mental equipment."

Medical men have been accused in the past, and still continue to be accused, of narrowness of outlook, of extreme professionalism; it is a charge which it is difficult for us to answer and one which is not wholly unmerited. This is all the more remarkable when medical education and training have been thought to be the most liberal education of all. But it is not only medicine which has to face up to this charge. As Prof. Whitehead once wrote:

"The fixed person for the fixed duties, who in older societies was such a godsend, in the future will be a public danger. In the second place, the modern professionalism in knowledge works in the opposite direction so far as the intellectual sphere is concerned. The modern chemist is likely to be weak in zoology, weaker still in his general knowledge of the Elizabethan drama, and completely ignorant of the principles of rhythm in English versification. It is probably safe to ignore his knowledge of ancient history. Effective knowledge is professionalized knowledge, supported by restricted acquaintance with useful subjects subservient to it. This situation has its dangers. It produces minds in a groove. Each profession makes progress but it is progress in its own groove."

"The effect of scientific thought during the nineteenth century was to attempt to subject all phenomena to measurement and classification: this has been the result of centuries of the growth and perfection of mathematics, and we passed from mysticism and philosophy to the cult of exactitude."

It is small wonder, therefore, that one of our sanest present-day medical writers, Prof. Major Greenwood, was impelled to write in his *Epidemics and Crowd Diseases*:

"I suppose the man who first exposed an animal to a high pressure of life-giving and life-sustaining oxygen and saw it go into convulsions and die had a shock. Perhaps the great biochemist, who a quarter of a century ago showed that animals supplied with all the necessary energy and building stones in the form of chemically pure proteins, fat, and carbohydrate, and the appropriate inorganic material—everything Victorian scientific hearts could desire—did not thrive may have passed through a moment of painful perplexity."

And now what next? We are still at the stage where we are unable to measure or classify all the aspects of *existence*, and so we are in danger of falling back upon philosophy once more for our explanations, as witness the growth of new and specialized sciences and philosophies. Perhaps we may be reaching a stage of regression or stagnation such as has occurred in the past, and this may even be a good thing to enable us fully to assimilate and use the plethora of "scientific" food set before us and to avoid the obvious danger of scientific indigestion. If I am right in thinking this, the need for a broader based education for us all—doctors and scientists alike—becomes more important.—I am, etc.,

Elton, Notts.

V. L. FERGUSON.

Care and Treatment of Elderly and Infirm

SIR,—The report of the B.M.A. Committee on the Care and Treatment of the Elderly and Infirm (*Supplement*, June 21, p. 133) is a promising but somewhat utopian document. One or two rather pressing questions remain totally unanswered by it. The first of these—Who is going to organize and run the geriatric departments?—will be hard to answer, since there are as yet only a mere handful of geriatric specialists. A second follows logically: How and where are we going to train our future workers in this field?

At present the average medical and nursing standards in the chronic and senile hospitals are low. Many changes will be necessary to give them either the equipment, the atmosphere, or the prestige which should belong to training schools. To

one practical example: many chronic hospitals have no physiotherapy department, yet physiotherapy is one of the corner-stones in the treatment and rehabilitation of the aged. In such a department, properly run, the famous 40, 40, 20 is not difficult to attain; without it the physician is blinded. This has been my own experience.

Similarly, specialists must be easily accessible. An orthopedic surgeon, an ophthalmic surgeon, and a neurologist are vital. I cannot recollect any mention of this vital need for team work being stressed in the report. Finally the mechanism for admission and discharge of patients, with arrangements for following them up, will need careful attention. Present municipal hospital practice is far from satisfactory in this respect, so that special machinery must be created with new long-stay annexes when they are formed. One last point: most of this report is concerned with the 5% of old folk in hospitals or institutions. Will it help the general practitioners who look after the remaining 95%?—I am, etc..

Reigate, Surrey.

TREVOR H. HOWELL

Health of Young Workers

SIR,—In the leading article entitled "Whither Industrial Medicine?" (June 14, p. 853) mention is made of the importance of health supervision of juveniles in industry. "In this alone," you state, "industrial medicine could make a significant contribution to positive health." It may therefore be of interest to note certain recommendations recently made by the Central Advisory Council for Education (England) in its publication *School and Life* (H.M.S.O., 1947). This Advisory Council was appointed by the Minister of Education under Section 4 of the Education Act, 1944, to advise "upon such matters connected with educational theory and practice as they think fit." By agreement with the Minister the Advisory Council addressed itself first to the transition from life at school to independent life, and, in this connexion, proposed measures for supervising health during the early years of employment; medical examination on entry should apply to all boys and girls up to the age of 18, and should lead to treatment, supervision, and guidance for all those found to be unfit; and to give effect to this the duty of making such an examination should be transferred to the school health service, which should also be responsible for treatment and supervision. In view of the definite challenge to industrial medicine so clearly presented in your leader it would be of value to hear your opinions on the subject from those both interested and personally taking part in health supervision of young persons at school, in the home, and at work.—I am, etc.,

Leeds, Birmingham.

C. H. HOSKYN.

Treatment of the Maladjusted Child

SIR,—Even if the statistics of the paper by Drs. Elizabeth W. Barker and W. Liddell Milligan (June 7, p. 805) are good, nevertheless I do not doubt the sincerity of their work and I am sure they are getting results. But two questions arise from their excellent work—namely: (a) Is a mental hospital better than schools or hostels for maladjusted children? (b) Do the children not come into contact through patients with psychological "mechanisms" and attitudes to which will cause more serious maladjustment in later life?

The authors did not state what conclusion they drew from the fact that they were receiving requests for admissions from all over England. Three conclusions will be difficult to exclude—namely, (a) ignorance by the source of the most modern methods of treating maladjustment; (b) correct knowledge at the source but absence of any place, such as schools or hostels, to put them; (c) economy. As things stand at present the Portsmouth people to be congratulated, but would a villa for the children alone be much better than the convalescent female villa? It would be logically difficult to put the convalescent females among children.

So-called psychosis in children (of normal intelligence) is practically always the result of provocation, overstimulation, or frustration in different directions, but it reacts well to association with normal adults in an environment where provocation and frustration are removed, even in cases with poor heredity. Uneducated and parents excepted, there can be few people more provocative to children than psychotic females.

In my opinion the best methods of training the maladjusted child (of normal intelligence) are in this order: (a) Out-patient attendance by father, mother, and child at child guidance clinic; (b) removal of father, mother, and children to a hostel (with the father going out to work from the hostel) for short periods, to be repeated in association with attendance at a child guidance clinic for longer periods; (c) removal of child to a residential school for maladjusted children accepted by the Ministry of Education; (d) removal of the child to a hostel (but local authority hostels have a long way to go before they reach the standard of efficiency of staffing, organization, and of material at the disposal of the good mental hospitals); (e) mental hospitals as an expedient or emergency.—I am, etc.,

Westcliff, Essex.

JOHN A. MCCLUSKIE.

Health of Children Attending Day Nurseries

SIR,—I am certain that Dr. F. Gray's letter (June 21, p. 899) will have inspired many medical women to take up their pens. I had hoped that the time had come when we could be accepted by our male colleagues as useful members of the profession. There are many women who believe they have a useful social function outside the home. Why such women should be denied the pleasure of marriage and children is something I cannot understand. I will not take time to refute Dr. Gray's conclusions, but I consider that those medical men who have worked with women doctors, nurses, pharmacists, etc., will know that they are neither "masculine" nor "irresponsible," and I am disgusted that a responsible journal like the *B.M.J.* has thought fit to publish such a letter.—I am, etc.,

London, N.W.5

BARBARA SIMONDS.

SIR,—From the business-like description of the masculine woman and her failings one may infer that Dr. F. Gray (June 21, p. 899) is in no position to appreciate the emotional difficulties experienced by one who has been trained for a "man's" job and is condemned by nature and society to reverse all her training and attempt the art of home-building and child-rearing. Certain women cannot help their lack of femininity any more than some men can remedy their lack of typically masculine characteristics. Each can only find out by experience what he or she can do competently, and in doing it make a true contribution to the sum of human happiness. Women are often acutely aware of their incompetence to understand a child's outlook, and they are not necessarily "irresponsible" in making a decision to place the children in the care of others who are willing, or are qualified by the State, to undertake part of the training that as mothers they have not been taught to understand.

If housework were considered by men to be a dignified occupation and child-rearing looked upon as a creative art, then the weaker members of the so-called stronger sex might find themselves eminently qualified to be home-builders, while their more robust wives became wage-earners. A good deal of masculine "ill-health and laziness" would thus be avoided, and the need for day nurseries considerably lessened.

A wife's lack of ability to be a "good mother" is the husband's greater opportunity to be a "good father." Marriage is a complementary status, each partner requiring of the other something necessary to the expression of individuality. If the true spirit of marriage is maintained, a right outlet for the energies of both should be established with no prejudice attaching itself to any job that either partner undertakes, so long as the aim and object of both is to create and maintain a home for their offspring. Zealots of health unfortunately lay themselves open to the error of putting asunder those whom a creative force has joined together, thereby lowering the strength of compassion to a nebulous pity which drains away mankind's capacity to evolve a higher form of life.—I am, etc.,

Newcastle-upon-Tyne.

G. M. LANGHAM-HOBART.

SIR,—The flood of letters abusing the day nurseries that Dr. Margaret E. McLaughlin's paper (May 3 and 10) has unleashed require a close scrutiny. I feel that the majority of them are inspired by a ferocity arising from a political prejudice and that they are much out of line when compared with the

usually well-conceived publications that are so characteristic of the English medical man's sane outlook.

Dr. McLaughlin's careful paper collapses on two most important points:

(a) The control group of children are those who live at home. Now these children come from a better type of home both from the point of view of mother's character and also financial stability, and they are therefore not true controls. Nobody is going to deny that the children living at home under the care of their mothers will be finer and fitter than the poor little soul bundled out of home at 7.30 a.m. come sun, come rain, inadequately washed, and often inadequately fed. But what are we going to do with the illegitimate child of the mother "forced to go to work"? These represent the majority of the children in day nurseries of which I have experience, not the absurd picture of the masculine mother in Dr. F. Gray's letter (June 21, p. 899). The "business executive" does not send her child to the day nursery. The day nursery children are certainly much better looked after in the nursery than allowed to run riot in the streets with the penny bun for lunch, or looked after by an already overworked neighbour.

(b) It is of course agreed that children *en masse* are more prone to infections one from the other. Why not, therefore, agitate against the kindergarten that the middle-class parents use? Obviously because it is unnecessary—unnecessary because those children come from a healthier and wealthier home than their more unfortunate brothers and sisters and can therefore withstand the onslaughts of infectious illness. Yet the day nursery and the kindergarten are strikingly similar. This, to my mind, proves that it is not the day nurseries that are at fault but rather the homes from which the nursery children are drawn.

I come now to my final point. In no papers that I have seen has there been an attempt to stamp out nasopharyngeal infections in the day nursery. Surely a healthy nose and throat will give the child a greater chance of avoiding infectious illnesses. Why not administer a routine nose drop as soon as the ubiquitous mucopurulent stream is seen tracking down the upper lip?

I should like to end with an appeal for a saner and less prejudiced outlook on the question of the children of the mother "forced to go to work." It will become even more urgent in the future as more and more women go into industry. —I am, etc.,

London, W.C.2.

J. Z. GARSON.

Treatment of Acute Mastitis

SIR,—While agreeing with Dr. J. MacLeod's treatment of acute mastitis (June 14, p. 865) by penicillin intramuscularly, I feel that routine stilboestrol is neither necessary nor desirable. I avoid using stilboestrol unless a milk fistula is present and the mother has stopped breast-feeding. From the figures given below the result is gratifying. The value of breast-feeding cannot be overrated, and we must avoid using any method whereby milk production is likely to be curtailed. The breasts can be adequately emptied by a breast pump.

The prevention of acute mastitis begins before the baby is born. Although the hygiene of the nipple is well known to the profession, it is sadly neglected in certain areas. In the majority of cases the aetiological factor is ascending infection from the nipple through the ductal system by *Staphylococcus aureus*, probably originating in the patient's skin. The use of penicillin cream during lactation is not desirable. It may have detrimental effects upon the baby, producing stomatitis and interfering with sucking. The introduction of penicillin has revolutionized the treatment of acute mastitis. It is no longer necessary to make large radial incisions into the breast to break down loculi to produce one abscess cavity from which pus can freely discharge on to the surface. The complications occurring after this method are haemorrhage, secondary wound infection delaying healing, and milk fistula. Frequent and repeated dressings are, both painful and tiring for the patient. Secondary suture means another operation and anaesthetic.

The principles of treatment of mastitis by penicillin are based on the pathology of the condition. All cases of mastitis and breast abscesses commence either as a diffuse suppurative or segmental mastitis. Penicillin acts by producing a localized suppurative mastitis. Depending on the quantity of pus present, either complete resolution or a chronic pyogenic abscess may occur. Thus, penicillin produces changes of chronicity, and when nature fails in severe cases to absorb the pus it is essential to realize this early and evacuate the abscess. I have used several methods to evacuate

the pus, having localized it in necessary cases by giving penicillin, 100,000 units in 1 ml. saline, twice daily for two to three days.

Penicillin Given I.M. b.d. in All Cases	No. of Cases	Organisms	Average No. of Days for Healing to Occur	Remarks
Incision and open drainage	20	<i>Staph. aureus</i>	16	1 milk fistula, 2 haemorrhage, 1 secondary infection with <i>Bact. coli</i> Slow healing of incision
Incision, with primary suture of wound, with corrugated rubber drain through it	3	" "	14	1 recurrent abscess
Incision, evacuation of pus, instillation of penicillin solution, and primary suture	2	" "	12	1 recurrent abscess
Incision, dependent drainage, and primary suture of wound	3	" "	12	Low grade infection of healthy area Residual induration
Incision, instillation of penicillin through penicillin tube, and primary suture around tube	3	" "	10	Low grade infection in healthy skin
Incision, penicillin tube through dependent area, and primary suture of wound	3	" "	11	Induration
Tenotomy incision and penicillin tube	20	" "	7	"
Multiple tenotomy incisions and penicillin tubes	1	" "	7	"
Secondary suture	Nil			

As the results of tenotomy incisions and penicillin tubes have been uniformly good in the 21 cases, I trust you will allow me more space to describe the methods. The smallest possible incision is made over the centre of the abscess with either a tenotomy knife or a narrow Bard Parker scalpel. The pus is gently expressed, and a narrow rubber tube stretched on sinus forceps is introduced into the abscess cavity. No suture is required to hold the tube in position, as the skin contracts tightly on it. Penicillin solution, 2,000 units per ml., is injected down the tube until the abscess cavity is filled. The tube is then spigoted. Penicillin, 100,000 units per ml. in saline, is given i.m. twice daily. The contents of the abscess cavity are aspirated twice daily and replaced by penicillin solution. After two to three days the aspirated fluid is clear and usually sterile. The tube is then removed and a penicillin dressing applied. In the event of the resulting cavity filling up again the contents can be gently expressed through the resulting sinus. Healing is generally complete on the sixth day, leaving a residual thickening in the breast. A good support is all that is now required, and after one to two weeks the thickening will have completely disappeared. If desired, short-wave diathermy will hasten this process.

In the presence of multiple abscesses separate tenotomy incisions and penicillin tubes for each abscess treated as above will give similar results.

I wish to thank Mr. Hugh Reid and Mr. A. C. Brewer for allowing me to carry out this treatment on their patients.—I am, etc.,

Liverpool.

R. MARCUS.

Treatment of Acute Osteomyelitis in Children

SIR,—It would appear from the letter of Drs. J. Trueta and M. Agerholm (June 21, p. 899) on the treatment of acute osteomyelitis in children by penicillin that they have approached the paper by Messrs. T. Twistington Higgins and Denis Browne and Dr. Martin Bodian (May 31, p. 757) with an air of complete disbelief. Having seen some of the results obtained at the Hospital for Sick Children, Great Ormond Street, and at Oxford, I am convinced of the efficacy of both the methods that are being advocated, but "each in its own place." It would seem to be wiser to take this broader view rather than to read more into the text than is apparent. Many of the remarks of Trueta and Agerholm appear rather out of context, especially those relating to surgery. Only two, or possibly three, of the Great Ormond Street cases warrant classification as "open surgery"; two could properly be described as cases of incision of superficial abscesses in an area in which the Oxford method is hardly applicable—as examples, in fact, of the time-honoured method of "free incision and free drainage" of a pointing abscess.

Aspiration is difficult, but the fact that repeated aspirations were needed does not imply that the method was unsuccessful. Many aspirations were needed in order that the amount of pus

present should constantly be minimal. Is it indeed certain that new pus does not form after drilling of a bone? With regard to dosage of penicillin: That advocated by Great Ormond Street does seem to be unnecessarily low. Presumably this is because the series was begun at a time when there was a dearth of the drug, and the dosage was continued because it was found to be adequate. It is a fact that immediate improvement occurred (i.e., within 24 hours) in the majority of the cases. Penicillin must obviously be given to infants by intermittent injection, and the fewer these are the better, provided that an adequate concentration be obtained and the best possible results, for trauma undoubtedly upsets infants and makes handling of them more difficult as regards feeding, etc.

Mobilization does not really form a large part in the treatment recommended. It is rather a suggestion that complete immobilization is unnecessary, and that simple methods are adequate in the acute stage. Certainly there would be little weight-bearing in the infant age group, and it is probable that the risk of pathological fracture is less than the dangers and difficulties involved in plaster immobilization in infants. With regard to positive blood cultures: this may be rather a false percentage, for no doubt some difficulties were experienced in obtaining some or sufficient blood in all cases. This point is not made clear in the article.

It would seem reasonable to accept, with reservations, the principles both of the Great Ormond Street and the Oxford series. It might be wise to use the Oxford method in older patients with severe infections, while the Great Ormond Street technique seems certainly to be adequate in the less severe cases, and in all infants in whom operations should not be undertaken too lightly, and in whom the difficulties of feeding, hydration, and so on have such an important bearing on the ultimate recovery. A dosage scheme dependent upon body weight would appear to be rational and desirable. Such a scheme has been started by Great Ormond Street in this series, and, though it has not yet attained general acceptance, it would seem to be more reasonable than a mere routine dosage for any patient of any weight and any age.—I am, etc.,

London, W.1.

IAN P. TODD.

Myiasis of Palpebral Conjunctiva

SIR,—I was interested to read Dr. T. E. M. Wardill's letter (May 3, p. 615) regarding myiasis of the palpebral conjunctiva. The following case came to my notice recently and may be of interest.

CASE REPORT

A soldier aged 20 reported sick on the evening of May 27 with an inflamed eye of a few hours' duration. He told the medical orderly that he could feel something moving about under the lid, and as the orderly could see something moving on the conjunctival surface he informed me.

On examination an acute conjunctivitis of the affected eye was evident, and on evertng the lids, to my surprise, a number of very tiny maggots were just visible. With characteristic dislike of light they wriggled away into the conjunctival fornices, but eventually half a dozen maggots were removed by wiping the palpebral conjunctiva with cotton-wool. One maggot was examined on the point of a needle, and its form was then clearly discernible. On questioning the man he stated that a fly had buzzed into his eye at 10 o'clock that morning, and the eye had become inflamed in the afternoon.

Following removal of the maggots his eye became more comfortable and the following day was quite normal.

The predominant fly around here is *Musca domestica*, but I am unable to say whether this might be the culprit or not.

I am indebted to Lieut.-Col. D. B. Seymour-Price, R.A.M.C., for permission to publish this case report.—I am, etc.,

P. DRANSFIELD,
Lieutenant, R.A.M.C.

M.E.L.F.

Acute Non-specific Diarrhoea and Dysentery

SIR,—I read the article by Dr. G. R. Kershaw on the above subject (May 24, p. 717) with pleasant anticipation, hoping to gain some new light on this difficult subject. I was disappointed to find that he appears to have drawn his conclusions after a few years' clinical observation, controlled by only a few full pathological investigations, and with an incomplete knowledge of the extensive literature already published. I have been investigating these cases at sea, as occasion offered, over the last twenty years. In most epidemics I have plated out the faeces, picked off non-lactose-fermenters, and put them through the appropriate sugar media, and tested their agglutination with

standard dysentery and salmonella antisera. I have never identified any pathogen from these cases.

In my paper in the *Lancet* (1938) reviewing this subject the question of chills, cold drinks, etc., was considered, but, after careful investigation, was not thought to be the whole answer, and no pathogen was found. My bacterial results were checked by the late Prof. Eyre, of Guy's Hospital. Drinking water was excluded after a research on the *Bact. coli* content of water in ships' tanks extending over a period of 18 months (Royds Jones, 1936). I note that Dr. Kershaw also exonerates water (after two analyses). Knowledge gained during the war when carrying troops in convoy allowed us to go a stage further (Royds Jones, 1943) and exclude food, water, and a food handler "carrier." It was due to this last letter that I was asked to meet the Director-General of Hygiene at the War Office, who kindly supplied me with a large quantity of media for an extensive research. Unfortunately owing to the progress of the war our route was changed, and we never again got these large epidemics in which 400 to 600 men were affected in one night, and I have not been able to proceed further. Incidentally, the majority of men affected were those sleeping in mess decks, both in hammocks and on the deck, and not those sleeping on open decks, where chilling would have been greatest, although some patients came from each.

My tentative suggestions at the time were either (1) a virus as the cause, or (2) a saprophyte becoming pathogenic at this temperature, for which there is some experimental evidence—Kligler, I. J. (1936), and Robertson and Weld (1932). I discussed the virus theory with a few first-class virus workers, and they at that time were inclined to discredit the suggestion. However, both American and Canadian workers had published papers suggesting a virus as the cause. Now British authorities are more inclined to favour this theory, as witness several articles published recently and your own annotation (Feb. 1, p. 187) about six months ago. I regret that I cannot give exact references to the recent literature, as I am now at sea.—I am, etc.,

Banbury, Oxford.

Primary Malaria in London

SIR,—The article by Drs. C. Blaxland Levick and M. E. MacGregor (May 31, p. 764) on "Primary Malaria in London Children" prompts me to write and bring to your notice a further case of this illness in an adult which I encountered during the week of publication of the original article.

The patient was a woman, aged 36, residing in Kensington and a Foreign Office Civil Servant employed at Eastcote. I saw her at home first on Thursday, May 22, 1947, when she was complaining of nausea with frequent vomiting, frontal headache, and lacrimation, back pain, and sweating. It was her belief that she had some form of "gastric flu." Her temperature was 101.4° F. (38.5° C.). The following day she was little better, and her temperature had dropped to 99° F. (37.2° C.).

On Saturday, May 24, she was moved to friends in Hampstead who were able to look after her better. She was feeling very much better, apyrexial, and thought she had recovered. Sunday evening, however, she developed a recurrence of her symptoms, which were now very much more definite in character and followed the typical stages of malaria, the temperature rising to 102.4° F. (39.1° C.).

Blood slides which were taken the following day when she was apyrexial proved negative; but those taken next day in the middle of a rigor were kindly examined for me by Dr. H. O. Hughes at the Middlesex Hospital, who reports that the films showed scanty trophozoite ring and amoeboid forms, and gametocytes of *Plasmodium vivax* (benign tertian malaria). She has since been given mepracine and remained free of symptoms.

Her history is interesting. Apart from travelling to and from her work daily she had not been out of London since last Christmas. She was born in India and resided in Calcutta till 1937, when she came to this country, and never had any form of antimalarial therapy given her at any time. The only illness in the past had been German measles, and 3-day fever when she was a schoolgirl aged 12—that is, 24 years ago, and a most unlikely factor in this illness. Her only contact with malaria

was this March, when a friend staying with her had a relapse in her home.

I hope that this case will help further in stressing the fact that primary malaria can be a factor in diagnosis in this country at the present time, where malarial carriers are more numerous and the *Anopheles maculipennis* known to be present.—I am, etc.,

London, W.11.

DAVID A. FERMONT.

Congenital Hepatic-duct Malformation

SIR,—The case of congenital hepatic-duct malformation recorded by Dr. Frank Riggall (June 7, p. 824) emphasizes the fact that children born without bile ducts, or with the bile ducts so malformed that they do not communicate with the intestine, survive much longer than one would expect. In Riggall's case the child lived for ten months, and in a large series of these cases reviewed by Stolkind¹ there was one where the child survived for 15 months. The question of operation is worth while considering in cases of atresia, for it may be found that sufficient of the common duct is present to allow of anastomosis to the duodenum. In these cases jaundice is usually present at birth or shortly afterwards, but according to Ladd and Gross² 2-3 weeks may elapse before the icteric tinge appears, "whereas the stools are always clay coloured or white from birth." Further, they state that if operation is delayed for 4-6 weeks from the date of birth there is little chance of error in differential diagnosis.

Anastomosis of the duct to the duodenum is carried out over a small piece of tubing—somewhat after the method of Sir James Walton³—and silk is used for suturing. Vitamin K and ox bile salts are administered beforehand in the hope of diminishing oozing.

Ladd and Gross emphasize the danger of post-operative disruption of the wound, and advise the use of silk and silkworm gut for stitching the abdominal wall. In 45 of their cases nine patients were found to have a patent hepatic or common bile duct connected with the intrahepatic ductal system but not with the duodenum; 6 out of 9 cases survived the operation and were in excellent health 12, 8, 7, 5, 4, and 3 years respectively after operation.

Dr. Frank Riggall is to be congratulated on taking the trouble of publishing his interesting case in the *British Medical Journal*.—I am, etc.,

London, W.1.

E.C.T.

SIR,—Your correspondent who explains (June 14, p. 858) his reactions to E.C.T. is to be highly congratulated for the enlightened description of his experience, and his article should do much towards alleviating the acrimony at present being expressed on the subject. His important contribution lies in the cognizance that the treatment produced a psychosomatic reaction which he himself "identified as the physical reactions to fear," as it is likely that it is through such identity that he escaped from his troubles. His "memory images" are obviously symbolic expression, which would have been better to have undergone elucidation at the time.

I hope I conflict with neither physicist nor psychiatrist when I understand that E.C.T. in this particular case acted by bringing wholly repressed material to a nearer level to conscious appreciation, and that it is probable that it is through such measures that benefit is obtained in all cases that respond to such treatment. Your correspondent's observations emphasize the further benefit to be obtained by the attendance of a psychiatrist to take advantage of the probability of such response.—I am, etc.,

Tipton, Staffs.

L. H. EUNSON.

Causalgia of the Face

SIR,—I read with interest Mr. J. A. W. Bingham's report of two patients suffering from causalgia of the face (June 7, p. 804). Our knowledge of this condition is so incomplete that individual experience is well worth recording. I cannot agree, however,

with his conclusion, "that when sympathectomy relieves causalgic pain and tenderness it does so by interrupting the sensory pathway." It is not proved that sensory (afferent) fibres travel to the spinal cord by way of the sympathetic chain, and secondly one can see that pressure on the superior cervical ganglion can stimulate efferent fibres passing through. "Novocain" block of these fibres at a lower level would produce a temporary paralysis in their peripheral course and distribution and so prevent the occurrence of pain as noted.—I am, etc.,

Sale, Cheshire.

C. H. CULLEN.

Reiter's Disease

SIR,—The annotation on Reiter's disease (Dec. 7, 1946, p. 865) summarizes the present state of the knowledge of this condition very well. A few points noted in four cases by me (subject of communication elsewhere) are worth mentioning. Though you have quoted several writers as correlating the disease with bacillary dysentery, Jackson's contrary opinion, which has also been quoted by you, seems to be confirmed by my four cases, none of which had any relationship with bacillary dysentery. Further, in India we see bacillary dysentery cases literally by thousands, and yet there are no authentic records of Reiter's disease. Had the two conditions been aetiologically related there would surely have been more cases of Reiter's disease in this country.

The categorical statement made by you that "... there is no relation to sexual intercourse" is not wholly correct. Kristjansen¹ described his case in detail in 1930 where the infection was traced to a girl of 16 who for two years had had a yellow vaginal discharge. This girl had also infected another man at about the same time, and the second victim developed only an uncomplicated urethritis lasting three months. In neither man was the gonococcus or any other organism found. The girl herself was examined and found to have had only an inflamed vagina, but gonococci were not demonstrated in her either. The sexual relationship in these two cases is clear. One of my four cases also developed the condition after extramarital coitus.

Neutrophil leucocytosis has been reported in all the cases, but one of my cases had an eosinophilia of 4 to 7% in a total leucocyte count of 11,000 to 13,000. This may mean that allergy is a factor in the disease. This case went through the gamut of bilateral conjunctivitis and polyarthritis, and the eosinophilia persisted over the earlier part of the illness. The patient did not have any parasitic infection or infestation. The possibility of allergy being aetiologically responsible is strengthened by the observation of Forbes² that his case was associated with dental sepsis. Junghans³ tells about a case in conjunction with a furuncle in the upper lip, while Frühwald⁴ described two cases, in one of which the first sign was urethritis and, in the other, joint pain in the left foot. The example of erythema nodosum being the result of a variety of infective processes may be mentioned as a possible parallel to the incidence of Reiter's disease following upon non-specific infections.

In none of the four cases observed was the complement fixation test for gonococci done, but gonococci were not found in any of the exudates by the usual staining methods. The tests were repeated many times and under varying clinical conditions.—I am, etc.,

Bangalore.

Physical Therapy of Mental Disorder

SIR,—It seems to the mind of an ordinary physician a great pity that there should be a need for bitter and violent controversies on the subject of psychiatry; I refer to the article written by Dr. D. W. Winnicott (May 17, p. 688) and to the replies by Drs. W. Malcolm Millar, Dr. A. Spencer Paterson, Dr. A. Lionel Rowson, Dr. A. N. Hardcastle, and Dr. E. E. Feldmesser (June 14, pp. 861 and 862). Whatever the rights and wrongs of it all may be, it seems to me that always should we be able safely to look to, and to accept, the findings and dicta of fully recognized and really experienced psychiatrists.

HAY FEVER

*can be readily relieved
by the application of...*

'ENDRINE' BRAND REGD NASAL COMPOUND

The application of a few drops of 'Endrine' into each nostril will soothe inflamed mucous membrane and effectively relieve the discomfort of hay-fever and the rhinitis of summer colds.

'Endrine' Ordinary formula: Ephedrine 0.75% w/w, Menthol 0.5%, Camphor 0.5%, Eucalyptol 0.5%, Oleum Ricini 0.35%, Light Liquid Paraffin ad. qs. 100%.

Available in 2 Varieties

BELLADENAL

**Antispasmodic .. Anticonvulsive
Sedative**

BELLADENAL combines the central sedative action of phenobarbitone with the peripheral antispasmodic action of the total laevorotatory alkaloids (Bellafoline) of Belladonna leaves. Bellafoline is only half as toxic as atropine in doses which are therapeutically equivalent in their effect on the parasympathetic.

Each tablet of Belladenal contains:

Bellafoline	0.00025 Gm. (1/250 grain)
Phenobarbitone	0.05 Gm. (3/4 grain)

The components of Belladenal act synergetically with each other so that a powerful antispasmodic and sedative effect is obtained with comparatively small doses.

DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE
indicated in

**Cardiac Decompensation, Oedema,
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart-muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Deriphyllin-Strophanthin is indicated for all cases of heart failure.

Available in liquid form for oral use,
ampoules and suppositories.

Literature and samples on request.

DIPHENAN B.D.H.

A Non-toxic, Non-staining Oxyuricide

Children with threadworm infestation are often subject to gastro-intestinal disturbances; thus, in the treatment of this condition, it is important to choose a medicament which is not likely to cause any further upset.

Diphenan B.D.H. is not nauseating, it is colourless and practically tasteless and its action on the parasite is established; Diphenan B.D.H. is, therefore, the most generally useful anthelmintic for use in threadworm infestation in infants as well as in children and adults. Further information will be supplied on request.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

Diphen/E/134

"Isn't there something I can take, doctor?"

Pretty often-heard question in these days of food shortages. The majority of the questioners probably do feel a real need to 'take something'.

Fortunately for those whose chief trouble is lack of calories, fats and vitamins, there is now no shortage of pure cod liver oil. SevenSeaS' trawlers have been back on the job for some time, so there is plenty of SevenSeaS cod liver oil in the chemists' shops for all who need it—both liquid oil and capsules.

For some time we have been trying, through advertising, to make people realise that our sea-fresh cod liver oil is a highly nutritious fatty food—the only one available in sufficient quantity to make good the cut in the fat ration, for example. Moreover, it is the only natural source of concentrated vitamins (A and D) which is both home-produced and plentiful. We are giving as much publicity as possible to these facts, in the hope that our efforts may in some measure help the public to combat the effects of continued "belt-tightening".

STANDARD OIL: Vitamin A 20,000 I.U.; Vitamin D 2,500 I.U. per oz.
CONCENTRATED: Vitamin A 60,000 I.U.; Vitamin D 6,000 I.U. per oz.

BRITISH COD LIVER OILS (HULL & GRIMSBY) LTD.
ST. ANDREW'S DOCK, HULL, ENGLAND

In my opinion, for what it is worth (I am not a psychiatrist), Dr. Winnicott's article is full of flaws, of wishful thinking, and of aggression. He condemns absolutely the modern physical methods of psychological medicine and is severely taken to task for it, as he should be. If I, practising my own methods of dealing with the emotional problems and upsets in children and in their parents, do not accept the principles of child guidance, and if I disagree in the main, as I certainly do, with most child psychiatrists and do not recognize the need for many of these, I am entitled to my opinion and quite free to say so. But if out of hand I condemn the whole movement and paint it as quite absurd, I think I should expect to be regarded as aggressive and, in all probability, somewhat frustrated: and I should certainly be incredibly foolish.

I scarcely think that Dr. Winnicott would be prepared to accept without retort my own condemnation (which, however, I do not offer) of the use of psycho-analysis in children, save in those cases which I personally would regard as uncommon. I think I should expect him automatically to express the view that I knew nothing about it.—I am, etc.,

London, W.1.

MAURICE L. YOUNG.

After-care of Psychiatric Casualties

SIR,—Most doctors are aware of the establishment about three years ago of the official after-care scheme for men and women discharged from the Services for psychiatric reasons. This scheme has been organized by the National Association for Mental Health at the request of the Ministry of Health with the co-operation of the Service Departments, and has provided social supervision for psychiatric casualties as part of an attempt to help them to readjust to civilian life—for 11,500 patients up to date. The original procedure was that the Service hospitals notified the after-care scheme of those patients who agreed to accept after-care, at the same time informing the patient's own civilian doctor. Subsequently many discharged ex-Service men and women have been brought into the scheme from a wide variety of hospitals and social agencies. In recent months, in response to many requests from other social agencies, Ministry of Labour, Pensions, and Health officials the scheme has accepted responsibility for a number of civilians who are in difficulties in ordinary life because of psychiatric disabilities. It is hoped that the experience gained in this social service will eventually be integrated into the official medical services of the State.

Whereas every effort has been made to see that the general practitioner has been fully aware of the interest of the social workers in his patient, this has not always proved possible. For instance, many patients on discharge from the service have moved to new districts and have not arranged for medical attention for many months after moving: some belong to that floating population which never remains for long with any individual doctor; others belong to the psychotic fringe hostile to any form of medical attention, yet nevertheless much in need of help. It has occasionally happened that doctors have felt that their relationship with a patient has been encroached upon by the social worker, of whose credentials they have not always been aware. In the great majority of cases doctors have been happy to use the services of our psychiatric social workers and have co-operated actively, but misunderstandings have occasionally arisen.

May I emphasize that this service is intended as an ancillary to medical measures, to aid in the patients' readjustment to life; and we regard it as of the utmost importance that good relationships should be maintained with general practitioners. Clearly, if misunderstandings occur, it hampers the efforts of both parties, and it is the patients who suffer. We have therefore arranged that each new patient referred to the scheme will be the subject of a letter written by the social worker to the doctor concerned. If the doctor has any comment to make or objection to raise he can do so at the outset, bearing in mind that after-care is a voluntary arrangement entered into by the patient himself. If doctors feel any doubts or questions about the validity of the work which the social workers are undertaking, we should be glad if they would ask the social worker concerned to call on them at their convenience to give a full explanation of what the service can offer. If further explana-

tion is needed, I and others of my medical colleagues who are active in this Association will be only too glad to get in touch with the doctors concerned.—I am, etc.,

KENNETH SODDY,

Medical Director,

London, W.1.

National Association for Mental Health.

Factors in the Aetiology of Skin Cancer

SIR,—I should like to ask Prof. J. A. Ryle and Dr. W. T. Russell whether the conclusions to be drawn from their interesting and instructive paper (June 21, p. 873) may not be subject to certain qualifications. Their figures refer to deaths from skin cancer, but the mortality rate from that disease is very low, probably less than 2%, while the disease itself is very common and accounts for a high proportion of all primary cancers.

Prognosis in skin cancer depends largely upon the size of the lesion, and negligence is probably an important factor in relation to death from this cause. I should, in the ordinary course of events, expect neglect of a symptomless lesion to be higher in unskilled workers and labourers (IV and V of the Registrar-General's social classes) than in the other groups. Do these figures therefore review a fair sample from which to assess the social or occupational factors in the aetiology of skin cancer?—I am, etc.,

Leeds

JOHN T. INGRAM.

Ulcerated Nasal Septum

SIR,—As medical officer to a large engineering firm, and during routine examinations of men who were working on a pickling vat containing sulphuric acid, I found that eight men were suffering from ulceration of the nasal septa. For treatment I tried petroleum jelly and lanolin, but the result was far from satisfactory. I changed the treatment after four days to cremor penicillin with "phenoxetol," and within forty-eight hours there was a definite improvement, and in twelve days with the exception of one case, the other cases were completely cured.—I am, etc.,

Birmingham.

JOSEPH RADNOR.

Calculation of the Colour Index

SIR,—It was inevitable that the publication of Dr. R. Elsdon Dew's paper (May 24, p. 723) would lead to your receipt of at least one letter calling for the abolition of the colour index. Admirable and well-meaning though Dr. H. Levy's intention may be, the widespread adoption of his suggestions (June 21, p. 903) in routine haematology would be regrettable, as not only does the use of the haematocrit involve vein puncture in a case where the life of the patient may later depend on the integrity of that vein for blood transfusion, but it tends to convert the haematologist into a mathematical robot. Haematology, no less than clinical medicine, is a science, and diagnosis should depend on the observation and experience of the haematologist, who, noticing for example marked polychromasia, "ghost-cells," scanty platelets, and other abnormalities in a routine blood count, then proceeds to carry out reticulocyte counts, fragility and haematocrit determination and so forth as his judgment backed by his clinical findings may dictate.

During the war years, when the country was flooded with innumerable varieties of lend-lease colour standards, each with its own level of normality, the use of the term "grammes" was probably justifiable and even desirable. The colour index of the Haldane scale is ideally suited for routine purposes, and with certain well-known exceptions normality is represented by unity and values outside the range 0.9 to 1.05 are—give accurate counting—probably pathological and certainly worth further investigation. The colour index is also a valuable guide to treatment of anaemias, where to subject the patient to repeated vein punctures would be wholly unjustifiable. Any improvements in the science of haematology should follow the lines of establishing specialist haematology departments in hospital laboratories, where the worker recognizes the abnormality by reason of his or her wide experience of the limits of normality.

Finally, the use of nomograms is to be condemned. The laboratory worker, whether he holds qualifications in medicine, science, or laboratory technology, is essentially a scientist, and any attempt to convert him into an automatic machine should be resisted at all costs. The slide rule and the centrifuge must not replace the microscope.—I am, etc.,

Liverpool.

WILLIAM K. TAYLOR.

Temporary Hydronephrosis

SIR.—The rate at which a hydronephrosis develops is an observation which can rarely be made, but I can assure Drs. Bruce Fowler and Eric Frankel (June 21, p. 887) that recovery from hydronephrosis does occur even when it results from chronic obstruction to the outflow of urine. This is well illustrated by one of my cases of carcinoma of the prostate, which on routine pyelography was found to have a bilateral hydronephrosis of considerable size.

Difficulty in micturition had been observed by the patient for several months, and acute retention had supervened, so that it is unlikely that the hydronephrosis was of recent development when it was discovered. It was actually demonstrated ten days before a suprapubic cystotomy was performed, and the diagnosis confirmed by section. Drainage of the bladder was continued for two months, after which time, under the influence of stilboestrol, he was able to pass urine freely. Intravenous pyelograms showed no trace of the hydronephrosis, and the suprapubic opening was allowed to close.

This case was originally seen at the end of 1943, and he still remains quite well on a maintenance dose of stilboestrol, with no evidence of renal damage.—I am, etc.,

Farnborough, Kent.

C. C. COOKSON.

State Medical Service in New Zealand

SIR.—May I, in fairness to both sides, be allowed the courtesy of your columns to add a footnote to the quotation of your correspondent, Sir Ernest Graham-Little (May 3, p. 611), from the *St. Mary's Hospital Gazette*?

I should like, in turn, to quote from a letter of Mr. Aleck Bourne which appeared in the *St. Mary's Hospital Gazette* of April-May, 1947. In this he said: "I predict that in twenty years' time the profession will look back on these past years and ask themselves how the present system of unco-ordinated muddle could ever have been allowed to exist so long as it has." This is the judgment of one of our most distinguished doctors and social reformers, who has perhaps contributed more in a practical way to the improvement of our health services than the great majority of people concerned with the new Act, whether in favour or otherwise.—I am, etc.,

E. C. LIVINGSTON,

Co-Editor, *St. Mary's Hospital Gazette*.

London, W.2.

Another Name

SIR.—It gives me great joy to see a letter from Dr. M. C. T. Reilly (June 21, p. 903) redolent of all his "mylophobia"—if I may coin a term to describe the mental attitude of those addicted to tilting at windmills. I feel as he does about the word "abmngnosia," but I am uncertain whether it is my mattering of the classics that is responsible. I feel that a word has no claim to be added to the language of Shakespeare if it is clumsy or ugly, no matter how pure its descent from nose of Plato and Cicero; and conversely that words, like poses, should not be condemned simply because they are hybrids. And "abmngnosia" seems to me to be both clumsy and ugly.

It is hard to suggest an alternative term. I for one would like occasionally to abandon Greek and Latin, and draw on our own literature: the term "Cheshire Cat Complex," conveniently abbreviated to "C.C.C.," might describe the condition. If we must stick to the classics, could we not give up the German habit of stringing words together until the resulting error is like a train of empty goods wagons, a thing without beauty, unity, or grace? A phrase is necessary to describe his state of mind, and I suggest *Mens sibi conscia sententiae*, which seems simple enough and is already three parts familiar.—I am, etc.,

J. N. FELL.

Colchester.

* * This correspondence is now closed.—Ed., B.M.J.

POINTS FROM LETTERS

The Tsetse Fly

Dr. G. PRENTICE (Fort Jameson, N. Rhodesia) writes: In the *Journal* of March 22 I turned to the letter (p. 388) on groundnuts in East Africa—not because specially interested in groundnuts but because it appeared to be from my old friend, Dr. J. B. Davey—to find that it dealt with another matter in which I have great interest, to wit, the tsetse fly problem. . . . Unless game can be driven to an altitude considerably over 4,000 ft. (1,220 m.), to drive them from one area into another (unless an unpeopled area) is sheer folly. They will only increase and multiply and sooner or later repeat the spread-out we have seen under protection whenever the costly measures required to hold them back are relaxed. At an altitude of 6,000 ft. (1,829 m.) I have never seen a tsetse fly, and there are excellent and extensive areas at about that height within the tropical belt. This great adventure in the production of fats for Britain deserves everything that can be done to make it a success. The animals destroyed to make success possible need not be wasted. In place of the "anthropological experts" I suggest canning experts, and that all meat not essential to the maintenance of the workers be canned or made into biltong and shipped home. Why search the Antarctic for whale meat when Britain owns the largest ranch probably in the world? . . . In Southern Rhodesia there are those who decry the policy there pursued, feeling as they do that the slaughter of wild animals is a very sorry business. But this extensive slaughter need never have taken place had the clean territories left us by the rinderpest epidemic been retained; and early warning was given that, when the time did come for indiscriminate slaughter to save human beings and domestic stock, the blame would lie not with those who opposed protection but upon those who put sport above everything else. There are two great scourges in Africa that, left to themselves to fight it out, might do so to the benefit of mankind in the long run. One is trypanosomiasis, which kills human beings and domestic animals. The other is rinderpest, which kills domestic animals and wipes out big game. Where it sweeps a district clean of game not a tsetse is to be seen. Now, our authorities have done everything in their power to prevent or eradicate rinderpest, which only slightly affects man, and I have never known of a fatal infection. Wild animals bring along tsetse; tsetse spreads trypanosomiasis; industries are impeded and human lives lost. . . . I fancy anyone clamouring for big game protection to the present Government would be barking up the wrong tree. Well then, why not add meat to the fat which the nut scheme envisages? Pack all the meat at present on the hoof where the clearings are to be, and to save the workers and feed the home folk do the same for ten miles around the groundnut areas—a first-rate health measure for home and here.

Shortage of Nurses

MISS JOAN MCCALLUM (London, S.W.19) writes: With reference to the letter of "Surgeon Commander, R.N." (May 24, p. 740) on the shortage of nurses: During seven years in Q.A.R.N.N.S. I frequently carried out instructional duties. I should like to point out the following facts to the Commander. (1) The orderly after his initial six weeks' training did not always enter the wards for practical experience but was allotted to non-nursing duties—i.e., pushing trolleys of medical stores, fire-watching, and messenger duties. This spoiled and deadened the enthusiasm of my keenest pupils. (2) When the orderly did enter the wards, he was at once taught to tremble and kneel down before the all-powerful god of paperwork, and so again missed practical experience. How can these men be suitable for inclusion on the *Register*? . . .

Financial Independence

Dr. W. CRAIG (Halifax) writes: The interests of the public and the interests of medical men already in State service (this is often overlooked) depend upon a strong independent profession. Independence in the long run is only possible if this includes financial independence, and the latter disappears the moment one's total remuneration comes from one source. This explains the paradox that, while N.H.I. has on the whole been a good thing for public and profession, its 100% extension would not be a good thing, as it would mean a profession not independent but wage-slave in type. Beware of attractive initial terms!

Tobacco

Dr. D. A. HERD (Leeds) writes: Allow me to congratulate Dr. Lennox Johnston on his excellent letter "Tobacco" (June 7, p. 827). Nowadays one sees health posters: "Spitting Spreads Disease," "Don't Cough," "Don't Spit," etc. If the public were advised "Smoke less," or better, "Don't smoke at all (except in your own house)," a great deal of the unpleasantness of smoking and spitting would be eliminated, and the benefit to health and mankind immeasurable.

Obituary

WILLIAM FIELDING ADDEY, M.D., F.R.C.P.

Dr. W. F. Addey died on June 20 at Otley, near Ipswich. He was born on April 23, 1872, the son of an Irish farmer; his mother was an Englishwoman. He was educated privately in Lanchester, and after leaving school was taken abroad by his mother, who was then a widow. He lived in Belgium, Germany, and France, and acquired a good working knowledge of both French and German. He was in Paris during the year when the hundredth anniversary of the fall of the Bastille was celebrated. The scenes he witnessed there made a deep impression on his youthful mind and did much to confirm the liberal outlook on social questions which was characteristic of him. In 1893 he matriculated at University College. Here he came into contact with, and was influenced by, E. V. Lucas, G. K. Chesterton, and A. E. Housman.

He soon decided that the profession of medicine would offer him the opportunities he sought for service to his fellows. He obtained the degrees of M.B., with honours in medicine, in 1900, B.S. in 1901, and M.D. in 1902; in 1925 he took the F.R.C.P. and ten years later was elected to the Fellowship. Addey acted as house-physician to Sir Frederick Roberts and as house-surgeon to Sir Rickman Godlee. His period of training before he went into general practice lasted for nine years, and he then joined a group of practitioners in Croydon with Dr. Parsons-Smith as the senior member. During the first world war he served for two years with the R.A.M.C. in France. When he was demobilized in 1919 he began to practise in Ipswich, where he found ample scope for applying his skill as a general and consulting practitioner. He was elected to the staff of the Suffolk and Ipswich Hospital, and later became consulting physician to it. He had been a member of the British Medical Association since 1903; and among other posts he held the office of president of the Suffolk Branch, 1932-3; representative in the Representative Body, 1934; and chairman, East Suffolk Division, 1935-6.

The claims of practice left him little time for engaging in his hobbies, the chief of which was sailing. These of his friends whom chance favoured will not soon forget the delightful experience of sailing with him in his yacht from the village of Pinmill near Ipswich to Harwich Harbour and back again between the wooded banks of the Orwell Estuary. He was fond of music, and he had a good collection of sets of the English classical authors, for he early acquired a love of literature. He keenly enjoyed foreign travel.

A friend writes, on behalf of his colleagues in Ipswich: We wish to give expression to our sense of the worth of the late Dr. Addey and of the loss we have sustained by his death. He came among us in middle life and soon made his presence felt in a way that was wholly acceptable to us. His advice was widely sought, particularly in cases of affections of the heart; he had made a special study of electrocardiography and had contributed valuable papers on the subject to the medical Press. His quick perceptions, his habit of thorough investigation, and his calm, considered judgment made him a helpful consultant. He had delightful personal attributes, including a keen sense of humour, which endeared him to all. A charming host and an equally charming guest, he combined the qualities of a great gentleman and of an able doctor. The efforts he made to carry on his work during the trying years of the recent war stand out as a shining example of tireless self-sacrifice. A serious illness about two years ago compelled him to retire from work, but after a gallant struggle he regained sufficient strength to resume his consulting practice. His end came suddenly and peacefully; after the busy life he led he has well earned his rest. We offer our sincere sympathy to his widow and two daughters in their bereavement.

Mr. DAVID JOHN EVANS, or "D.J." as he was known to so many of his associates, died on May 20. He was in his early fifties, but an extremely active clinical life had for the last ten years been interfered with by ill-health; periods of intense surgical activity, which in earlier days had been his routine, were followed by recurrences of his complaint, and yet he bore

these setbacks cheerfully. After receiving his medical education at Birmingham University, where he qualified in 1913, he served in the R.A.M.C. and then went to China. From 1922 he was assistant professor of oto-laryngology at Shantung Christian University. He returned to England after five years, but his work in the mission field had left its stamp on "D.J." and moulded his manner of life. After obtaining the F.R.C.S. in 1927 he joined the staff of the Birmingham and Midland Ear and Throat Hospital, and a year afterwards that of the Queen's and United Hospital; ill health caused him to give up the latter appointment. For many years he was aural surgeon to the Birmingham education committee and a consultant to several charitable institutions. He was honorary secretary of the Birmingham Central Division of the British Medical Association from 1930-5, and chairman of the Division in 1935-6. He had been an active member of the Association for twenty-eight years.

Dr. FREDERICK CANT, who was 85, died on May 22 at his home in Woodley, near Stockport. At the age of 22 he came from London as an assistant to Dr. Smith of Woodley after being apprenticed to Dr. New for four years. A student of Owen's College, Manchester, he qualified in 1888, and was for twelve months a resident at Stockport Infirmary. During his apprenticeship he had attended more than 200 midwifery cases, an experience which proved invaluable in his long career as a family doctor. On the death of his principal, he took over Dr. Smith's practice. In those early days he paid all his visits on horseback but was one of the first to take to motoring. He was medical officer of health for Bredbury and Romily U.D.C. for 48 years, retiring when a full-time M.O.H. was appointed in 1938. He was also district medical officer to the Board of Guardians and the Post Office, and served as medical officer for one part of the Manchester Ship Canal during its construction. Dr. Cant joined the British Medical Association in 1890 and was also at one time president of the Stockport and District Medical Society. In 1915 he was elected the second chairman of the newly formed Hyde Division, a division inaugurated on the eve of the first world war. He held office for three years and gave valuable service as chairman of the Local Medical War Committee. He acted as M.O. to the 6th Battalion of the Cheshire Volunteers. Dr. Cant was a devout churchman and for many years a churchwarden of St. Mark's Church, Bredbury.

Mr. WILLIAM EVERETT died suddenly at the Royal Hants County Hospital on June 15 at the age of 56. Mr. Everett qualified M.B., Ch.B. at Edinburgh University in 1917 and took the F.R.C.S. Ed. two years later. He had been house-surgeon at the Edinburgh Royal Infirmary and demonstrator of anatomy at the University. He was later R.S.O. at Bradford Royal Infirmary and had contributed a number of articles on surgical subjects to this and other journals. He had been a member of the British Medical Association for twenty-seven years.

K. M. R. writes: By the sudden death of William Everett, the profession has been severely hit, for his technical skill and his wise and often inspired judgment placed him in the front rank. It will be difficult to replace him in the county where his work was done. For nearly twenty years he had served on the honorary staff of the Royal Hants County Hospital, Winchester, and his long and ever lengthening waiting-list spoke eloquently of his popularity. A wide circle of professional friends had grown to know his skill and ability, and to depend upon him in a way that is not often experienced. These will feel his loss acutely. This confidence was shared in a high degree by his patients, for he had in generous abundance the power to instil confidence at very short notice. His surgical judgment was unflinching, and his technical ability was of a very high order. He was a joy to watch, and a model worthy of the closest emulation. Those who have had the good fortune to work as his house-surgeons have recorded with pride and gratitude their lasting indebtedness to him. His appetite for work was hard to satisfy and remained with him even when indifferent health made his long operating lists a heavy burden. His loyalty to colleagues who had sent patients to him made it difficult for him to delegate work, and he strove to the very end to reduce the grotesque numbers on his waiting-lists, a struggle which was doomed to failure, for his popularity never ceased from growing, and as the years passed he became more and more in demand. He was a great surgeon and one who would have found himself in the front rank wherever his work was done. But he will be mourned and missed for more than professional qualities. So many will recall with gratitude his outspoken opposition to injustice. Many more will recall his loyal friendship and the ease with which he gave the benefit of the doubt to what was good, rejecting the less good. His interests were wide. In earlier days he had played golf from

scratch and could hit a tennis ball hard and straight. He loved his garden, and it was a joy to behold, while his knowledge of pewter and his personal collection were outstanding. He seemed happiest in his home, and watched with great pride the promise of his son and daughter, while his constant care of a wife who had been through a long illness was good to see. It will be a long time before the gap his death has made will be filled, for he had made for himself a unique position in the professional and social life of his city. He was as dearly loved as he was admired, and the writer's feeling of deep personal loss will be shared by many.

Mr. L. Z. Cosin writes: Although the obituary notices of Prof. NOAH MORRIS have paid due praise to much of his work, I do not think it is sufficiently widely known how great his interest in the medical care and general welfare of all old people had been latterly. In addition to stimulating general interest in the geriatric work in his own hospital, Prof. Noah Morris had instituted several interesting and original approaches to research in this subject. Meeting him regularly at a small Ministry Committee considering this problem, we were all struck by the warm humanity and medical skill he brought to bear on this pressing subject.

V. A. writes: It was with the deepest regret I saw the death of Prof. A. F. BERNARD SHAW reported in the *Journal* of June 21 (p. 904). To Durham students who had the privilege of his teaching during the years when his health was relatively good, he will be unforgettable. He combined a passion for his subject which he endowed with almost the grandeur of the heroic saga, with an intense hatred of all that was petty and slovenly. We will remember him with gratitude for the inspiration which he gave us as a teacher, for the kindness and encouragement which he gave us individually, and for his refusal to compromise with anything falling short of the highest standards of our profession.

Medico-Legal

A LONG GESTATION PERIOD

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

English law dislikes rigid rules of evidence binding the court to presumptions of fact. For instance, whereas the law of several foreign countries lays down limits for the possible period of gestation, our law knows no such limits and our courts have consistently refused to fix one. In the case of *Clark v. Clark*¹ the President, Lord Merriman, refused to hold that a child was illegitimate which survived after an apparent pregnancy of 174 days. At the other end of the scale the court held in *Gaskill v. Gaskill*² that 331 days was not too long a pregnancy to admit as possible. Even this record was broken in the recent case of *Wood v. Wood*.³

A wife summoned her husband before the justices for desertion. The husband's defence was that he was not bound to continue to live with his wife because she had committed adultery. Evidence was given of the last date on which the couple actually cohabited, and of the birth of a child, fully grown and somewhat over the average weight, 346 days afterwards. The husband called no evidence of any association between the wife and other men, but maintained solely in view of the length of the gestation that the child could not be his. The magistrates, rightly considering that the allegation of adultery is serious and must be strictly proved, refused to assume adultery on the gestation period alone, but accepted the evidence of the wife denying it.

The president of the Divorce Court, hearing the husband's appeal, agreed that there must come a point at which any judge must take judicial knowledge of the fact that the period is altogether outside what is possible, and also that one case or another must be on the wrong side of any line that can possibly be drawn. He absolutely declined, however, on the information before the court, to say that it was bound to hold that 346 days was on the wrong side of any line that could possibly be drawn and that the wife had committed adultery. The court also held

that, although the husband believed that the wife had committed adultery and that he was not the father of her child, he had nevertheless deserted her, because his belief was not induced by such an act on her part as would lead a reasonable person to believe that she was guilty of adultery. It therefore upheld the order of the justices requiring the husband to maintain the wife.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

On June 12 the honorary degree of D.Sc. was conferred on Sir Edward Mellanby, K.C.B., M.D., F.R.S., Honorary Fellow of Emmanuel College and Secretary of the Medical Research Council. On June 17 the degree of M.D. was conferred on M. S. M. Fordham.

The following candidates have been approved at the examination indicated:

FINAL M.B.—Part II (*Principles and Practice of Physic, Pathology, and Pharmacology*): A. Ackroyd, W. E. C. Astle, A. P. C. Bacon, W. H. Barker, H. B. Barlow, W. Beattyman, S. B. Bennett, G. A. Bracewell, R. W. Brown, M. A. J. Browne, J. H. S. Buchanan, J. D. Burion, H. W. Cornford, A. F. Crick, M. de B. Daly, R. J. Dickson, A. B. Douglas, M. C. Edmond, D. M. Evans, G. R. Faber, A. S. Fairbairn, A. W. Ferguson, N. B. Finter, D. K. Ford, W. D. Foster, A. G. Freeman, J. H. Garson, K. O. George, R. V. Gibson, J. G. Goodhart, C. L. Grandage, J. L. Hansell, P. A. S. Hargrove, M. Harington, J. L. Harris, R. E. D. Harvey-Samuel, F. G. Herman, C. F. Hingston, C. W. Hollingsworth, S. H. F. Howard, G. W. C. Johnson, H. B. Kidd, R. G. Law, I. S. Longmuir, J. M. S. McCoy, J. McFie, L. E. McGee, I. C. K. Mackenzie, I. D. Mackichan, G. T. B. Mackinnell-Childs, K. M. McNicol, G. C. Manning, J. L. Moffatt, D. C. Morley, T. G. Osmond, J. M. Palmer, J. K. P. Perera, E. E. Philipp, G. S. Plaut, R. C. S. Pointon, R. H. B. Protheroe, P. K. Pybus, R. C. Read, D. H. Richards, E. T. Roberts, A. W. Robinson, R. A. Robinson, M. G. Rolfe, A. J. Russell, E. Sherrah-Davies, E. P. H. Shortt, R. S. Smylie, W. Spector, M. P. Spence, F. C. Siallybrass, I. W. Stoddart, G. W. Sykes, N. Tate, G. E. Thomas, P. G. Trehan, J. A. Tutton, M. H. D. Veale, L. G. R. Wand, A. P. Waterson, J. S. W. Whitehead, A. J. W. Woodroffe, P. M. Yap, P. M. Yeoman, R. E. V. B. Young. *Women*: J. M. Cockrell, J. Crossley, P. E. Davis, L. A. Farquharson, J. K. Goodacre, H. A. Jaques, I. Kane, Mrs. P. D. Kilner, R. M. Licence, Mrs. M. R. Simpson, S. G. Wills.

UNIVERSITY OF LONDON

Sir Francis Fraser, M.D., F.R.C.P., director of the British Postgraduate Medical Federation, has been appointed Deputy Vice-Chancellor of the University for 1947-8.

Kenneth James Franklin, D.M., F.R.C.P., has been appointed to the University Chair of Physiology tenable at St. Bartholomew's Hospital Medical College, from Oct. 1.

The degree of D.Sc. has been conferred on W. J. Martin, an internal student of Birkbeck College and of the London School of Hygiene and Tropical Medicine.

Sir Herbert Eason has been reappointed to represent the University on the General Medical Council for a further period of three years from November, 1947.

Prof. Hamilton Hartridge, M.D., Sc.D., F.R.S., resigns from the Chair of Physiology at St. Bartholomew's Hospital Medical College, as from Sept. 30.

The following have been recognized as Teachers of the University in the subjects indicated in parentheses. *London Hospital Medical College*: Mr. A. Bowen-Davies (Oto-Rhino-Laryngology); Mr. H. Osmond Clarke (Orthopaedics); Mr. A. J. King (Venereal Diseases); Dr. K. M. A. Perry (Medicine); Dr. W. S. Tegner (Physical Medicine); Mr. V. C. Thompson (Surgery). *Guy's Hospital Medical School*: Dr. P. M. F. Bishop (Medicine). *St. George's Hospital Medical School*: Mr. A. H. Charles (Obstetrics and Gynaecology); Dr. T. Crawford (Pathology); Dr. J. F. Dow (Medicine); Dr. E. Miller (Mental Diseases); Mr. A. H. M. Siddons and Mr. E. R. Smith (Surgery); Dr. D. J. Williams (Medicine); Mr. R. H. Young (Orthopaedics). *Royal Free Hospital School of Medicine*: Miss Dorothy J. Collier (Oto-Rhino-Laryngology); Dr. Katharine G. Lloyd-Williams (Anaesthetics); Dr. Dulcie C. Staveley and Dr. E. U. Williams (Radiology); Mr. R. H. Maingot (Surgery). *University College*: Dr. W. A. Fell (Anatomy). *University College Hospital Medical School*: Dr. W. Moodie and Dr. F. Dillon (Mental Diseases); Dr. E. E. Pochin (Medicine). *National Institute for Medical Research*: Dr. A. A. Miles (Bacteriology, Immunology, and Hygiene). Dr. D. C. Shields has been granted probationary recognition as a Teacher of Physical Medicine at St. George's Hospital Medical School for two years from February, 1947.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Dr. W. K. Livingston, professor of surgery in the University of Oregon, will deliver a Moynihan Lecture at the College (Lincoln's Inn Fields, W.C.) on Tuesday, July 8, at 6.15 p.m. His subject is "Physiological Responses to Wounding."

'KEMITHAL' SODIUM

'Kemithal' Sodium (sodium cyclohexenyl-allylthiobarbiturate) is a new ultra-short-acting intravenous anaesthetic, evolved in the I.C.I. Research Laboratories.

In extensive clinical trials, 'Kemithal' Sodium has proved to be a highly efficient and satisfactory agent for basal hypnosis and for surgical anaesthesia of short or prolonged duration.

Having a relatively high therapeutic quotient, 'Kemithal' Sodium effects anaesthesia without undue respiratory depression. A number of workers have commented upon the reduced incidence of laryngeal spasm with 'Kemithal' Sodium.

Literature on request.

'Kemithal' Sodium is issued in ampoules of 1 gramme and 2 grammes in boxes of 5 and 25, with or without sterile distilled water in ampoules of 10 c.c. and 20 c.c. respectively; ampoules of 5 grammes 'Kemithal' Sodium are also available in boxes of 5 and 25.

CROOKES LACTALUMINA...

Roentogram showing site of Gastric Ulcer

The logical treatment of peptic ulcer includes the control of acidity and pepsin activity throughout the twenty-four hours.

THIS can be achieved by giving: (a) Food (which buffers the acid and uses up the pepsin) and (b) Lactalumina (which inactivates the pepsin and neutralises the acid). Lactalumina (2-4 teaspoonfuls), or food, should be given every hour throughout the day with at least two tablespoonfuls of Lactalumina at bedtime, the dose to be repeated once or twice during the night.

Full literature on request.

NOVUTOX

Self-Sterilising
LOCAL ANÆSTHETIC

½%, 1% & 2% SOLUTIONS

FOR

MINOR & MAJOR SURGERY

Absolutely non-toxic in therapeutic doses and tolerated by even the most sensitive tissues, Novutox has the added advantage that it possesses a remarkable chemo-therapeutic action which promotes very rapid and clean healing of wounds.

Available in:

½%, 1%, and 2% Solutions: - - - BOTTLES of 2 ozs. and 20 ozs.
1% and 2% Solutions: AMPOULES 2 c.c. Boxes of 12 and 100.
CARTRIDGES of 2% Solution are available in boxes of 20 and 100.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.0002 gm. epinephrine and 0.0002 gm. capryl hydrocupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

Vitamin Therapy —its uses and limitations

A SINGLE SUPPLEMENT FOR SAFER PREGNANCY

Adequate safeguards against the hazards of pregnancy are now routine in practice. Among these, the provision of priority supplies of essential foods to pregnant women has had a significant effect in reducing maternal and infant mortality. Cases still occur, however, in which full advantage is not taken of these allowances. Where patients are found to be anæmic, debilitated or showing signs of sub-normality in respect of the protective factors, the simplest prescription for ensuring an adequate intake of all the necessary nutrients is that of

PREGNAVITE

The recommended daily dose provides:—

vitamin A 4,000 i.u.	vitamin E 1 mg.	iodine	} not less than 10 p.p.m each
vitamin D 300 i.u.	nicotinamide 25 mg.	manganese	
vitamin B ₁ 0.6 mg.	calcium 160 mg.	copper	
vitamin C 20 mg.	iron 68 mg.

in sulphonamide therapy...

lower dosage

greater safety

... are provided by 'Sulfamerazine' which requires only approximately one half the usual dosage of sulphadiazine or sulphathiazole.

This reduces sulphonamide therapy to simpler and more economical terms.

In diseases in which four to six doses of sulphadiazine or other sulphonamides are given daily, the same therapeutic results may be obtained with a minimum of inconvenience and at proportionately lower cost, by only two to three doses of 'Sulfamerazine'.

- (1) Relatively infrequent and smaller doses are required to maintain any given plasma concentration.
 - (2) The urine concentration at any given blood level is less than that of other sulphonamides in current use.
- drug concretions
Sulfamerazine
sed.

'Sulfamerazine' is no more toxic than sulphadiazine and less toxic than sulphathiazole and sulphapyridine. It is remarkably effective in the treatment of infections caused by pneumococci, hæmolytic streptococci, meningococci and gonococci.

'Sulfamerazine' is supplied in 0.5 gm. tablets for oral administration, in bottles of 50, 100, 500 and 1000. Sodium 'Sulfamerazine' sterile powder for intravenous administration is supplied in 5 gm. vials and in 50 c.c. ampoules of a 6% solution. Descriptive literature and dosage schedule on request.

SULFAMERAZINE

SHARP & DOHME LTD., HODDESDON, HERTS.

At an ordinary meeting of the Council of the College, held on June 12, with Sir Alfred Webb-Johnson, Bt., President, in the chair, it was announced that a Supplemental Charter had been granted to the College, giving power, among other things, to co-opt additional members of the Council, to conduct a special Final Fellowship examination in ophthalmology and otolaryngology, to grant a Fellowship in Dental Surgery, and to institute faculties in the College.

The following were co-opted members of the Council for the ensuing year: Dr. H. Guy Dain (General Practice), Mr. G. F. Stebbing (Radiology), Mr. V. E. Negus (Otolaryngology), Dr. A. D. Marston (Anaesthetics), Mr. George Black (Ophthalmology), Mr. R. V. Bradlaw (Dental Surgery), Mr. L. Carnac Rivett, subject to the result of the Council election (Gynaecology and Obstetrics).

Mr. R. J. McNeill Love was appointed as representative of the College on the British Social Hygiene Council.

Diplomas of Fellowship were granted to the following successful candidates:

allough, R. Petticrew, K. G. Rotter, A. W. L. St. J. M. C. Birt, J. V. Crawford, G. R. Crawshaw, Birmingham, F. B. Cockett, R. E. Shaw, H. M. Lewis, M. T. Phelps, J. J. Shipman, J. G. Taylor, F. T. Wheelton, K. W. Wilkinson, B. B. Milstein, D. J. Robertson, S. G. Tuffill, D. P. Choyce, R. Anthonis, D. B. Brown, R. T. Campbell, M. Chaudhuri, L. P. Clark, R. L. Cooke, J. B. Curtis, E. T. Dick, J. L. Dowling, Marjorie O. Dunster, S. M. Ghosh, N. O. K. Gibbon, W. Girdwood, A. J. P. Graham, R. T. Grime, W. G. Hendry, J. P. Herdman, C. Hollenberg, B. Lewin, G. M. Lewis, E. T. McCartney, S. T. McCollum, D. McIntosh, A. M. Lair, H. L. C. Maitland, P. E. Marchand, R. P. Melville, H. D. Moore, E. J. Nangle, S. M. Nawab, G. E. Nevill, J. S. Peters, S. F. Reid, R. B. Scott, R. A. Stephen, H. D. A. Sutherland, R. A. R. Taylor, G. J. Walley.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

D. V. Bateman, O. H. Belam, C. H. Boyd, W. H. F. Boyd, P. R. Bromage, E. K. Brownrigg, R. Bryce-Smith, J. E. Bulow, D. Canter, A. A. Cithers, R. B. Clayton, F. E. Clynick, S. W. Collin, E. R. Coleman, P. B. Conroy, C. J. Corcoran, G. Curd, R. M. de Gregory, A. B. Eastwood, I. C. W. English, J. A. Forbes, A. Fraser, Eileen McC. Gibson, L. J. Goggin, J. Gordon, A. H. Grace, P. W. S. Gray, H. Grenville, J. H. G. Halliday, J. K. Harper, J. W. Hind, A. C. Holmes, H. R. Hudd, G. Hughes, R. McD. S. Keir, J. Lapraik, C. H. Levick, J. K. Lewis, Mary E. Lloyd, R. E. Loder, J. M. MacCormack, R. M. Mackenzie, R. L. McMillan, S. A. Mason, J. G. Matheson, E. T. Moersch, P. H. Moore, W. B. Neff, G. S. Osler, W. J. Patterson, J. Psaila, H. J. Richardson, Hilda Roberts, J. D. Robertson, F. R. Russell, C. F. Seurr, E. Thomas, T. C. Thorne, C. E. Tudor, Ambrosine B. Vaughan, Patricia E. Wallace, Mary Watson, H. L. J. Wilson, G. P. Williams, T. M. Williams, T. N. P. Wilson, E. H. Winterhoutom, Luise Wislicki, R. B. Wright.

A Diploma in Medical Radio-diagnosis was granted, jointly with the Royal College of Physicians of London, to R. L. T. Hill (Glasgow).

A Diploma in Child Health was granted, jointly with the Royal College of Physicians of London, to S. Ray (Calcutta Medical School).

A series of lectures on anatomy, applied physiology, and pathology will be delivered at the College from Monday, June 30, to Thursday, July 31, and from Monday, Sept. 1, to Tuesday, Sept. 16 (Saturdays and Sundays excepted), at 3.45 p.m. and 5 p.m. each day. The fee is £16 16s. Fellows and Members of the College and Licentiates in Dental Surgery will be admitted for £12 12s. Admission cards may be obtained from the assistant secretary of the College.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the meeting of the President and Fellows of the Royal College of Physicians of Ireland held on June 6 Dr. Eamonn de Valera and Dr. J. Browne Fleming were admitted Fellows and Dr. P. M. Alston, Leslie Doyle, Leslie Fridjohn, Alan P. Grant, George Gregg, John Hayes, P. D. J. Holland, W. Dillon Hughes, Sean D. McGrath, Harry O'Flanagan, and Bethel E. R. Solomons Members of the College.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College, held on May 31 with the President, Mr. W. Gilliat, in the chair, it was announced that the Rt. Hon. Field Marshal Jan Smuts, P.C., had accepted an invitation to become an Honorary Fellow.

To mark the grant of the Royal Charter of Incorporation on March 21 the following four surviving signatories to the Articles of Association, whereby the College was founded, were elected to the Honorary Fellowship: Prof. J. M. Munro Kerr, Prof. C. G. Lowry, Sir Ewen Maclean, and Sir William Fletcher Shaw.

The following were elected to the Council to replace those retiring in statutory rotation: As Representatives of the Fellows, D. Baird (Aberdeen), Alice Bloomfield (London), G. I. Strachan (Cardiff). As Representatives of the Members, J. A. Sialworthy (Oxford), A. M. Sutherland (Glasgow), R. J. Wotherspoon (Glasgow).

A standing committee of the Council, to be known as the Australian Regional Council, has been set up in Australia, with Dr. F. A. Maguire (Sydney) as chairman, to act as a representative committee of the council of the College in discussions and negotiations affecting the practice of obstetrics and gynaecology in Australia.

Prof. B. T. Mayes (Sydney) will act as honorary secretary of the Australian Regional Council.

The following were admitted to the Fellowship of the College:

M. D. Black, J. S. Hovell, J. Jhirad, T. N. MacGregor, R. Newton, G. D. Shaw, G. S. Smyth, H. S. Walters, B. Williams.

The following were admitted to the Membership of the College:

D. Ballantine, Margaret R. Biggs, W. S. Campbell, J. B. Cochrane, S. J. Cohen, H. V. Corbett, A. Davis, J. R. Dickinson, Bessie Dodd, Morag Dods, R. C. Gill, Jean L. Hallum, R. S. Lawrence, T. H. Lawton, J. M. McBride, R. A. E. Magee, M. K. O'Driscoll, S. F. Pooley, L. J. Quinn, R. B. Salter, P. C. Thomas, Kathleen M. FitzG. Worrall, J. L. Wright.

Medical Notes in Parliament

V.D. in British Forces

Dr. SEGAL, on June 25, discussed the incidence of venereal disease in British Forces overseas. He said the British soldier was less prone to V.D. than the soldiers of any other Allied force. He believed statistics which had been given lately in the House of Lords (*Journal*, June 14, p. 867) were unreliable, because though they dealt with incidence of the disease over 12 months per 1,000 men in a Command they failed to take account that these men were in a mobile state through postings and replacements, so that their numbers were considerably increased. The real problem was how far risks of infection had been taken for every recorded case of disease. With wide dissemination of knowledge, with well-known methods of prophylaxis and early treatment, and with a relatively low proportion of relapses and recurrences, the figures actually given were symptomatic of a general loosening of moral ties which affected many countries beside our own. He asked how the Secretary for War explained a rate of incidence of V.D. in the Far East six times as high as in the Middle East. Why was the rate in Germany and Austria to-day almost five times as high as in the Middle East? More could be done in regard to the branches of the Services which dealt with the moral and cultural well-being of men in the Forces, and welfare activities by civilian agencies should be encouraged more, even in occupied territories.

Mr. JOHN FREEMAN, replying for the War Office, said Dr. Segal's approach to the problem was correct. The difficulty could only be overcome by making conditions in the Services overseas such that the temptation leading to this scourge was less likely to arise. There tended to be a periodic rise in the incidence of the disease after a war, and a peak period which the Forces had now perhaps passed. For the first quarter of 1946 the Rhine Army figures were 30.4 per 1,000; for the second quarter 41.8; for the third quarter 44.6; for the fourth quarter 41.8, and for the first quarter of 1947 30 per 1,000. He hoped the decline would be accelerated. The increase in the middle of 1946, the reduction at the end of last year, and in the beginning of this year were substantially reflected in the Commands. These were terrible figures, but lower than for a similar period after the first World War, although men were now more ready to report this disease. He could not give a clear answer to show why the incidence of the disease should be lower in the Middle East, but Service conditions there, substantially removing the men from female companionship, had a great deal to do with it. In Germany, Austria, and the Far East conditions were conducive to V.D., and its incidence among the civilian population was high. Only recently had the Army started to make progress in controlling sources of infection in the Far East. It had more civilians doing welfare work abroad than it had during the war. It was obvious that, although medical methods could limit the seriousness of the problem, the way to eliminate it was by a moral, educational, and welfare approach.

Central Purchase of Hospital Equipment

Mr. HAYDN DAVIES, on June 26, asked the Minister of Health to what extent it was proposed to obtain equipment and supplies for hospitals under the National Health Service by centralized purchase in place of the present system of purchase by individual hospitals; and whether a similar policy would be applied to installation and maintenance services.

Mr. BEVAN answered that hospital equipment and supplies covered a wide range. For some items, there might be advantage in central purchase. But where present methods of supply and servicing worked satisfactorily it was not proposed, at the outset of the new Service, to interfere with them. For the time being central purchase would be limited to major

equipment which was in short supply, and various other items which might be found to lend themselves to central purchase on grounds of economy or better efficiency.

Negotiations with the Minister

On June 26 Dr. SEGAL asked whether any interim report would be issued to the House on the progress of negotiations with the Negotiating Committee of the medical profession; and when this interim report could be expected.

Mr. BEVAN said there would be no such issue. He expected that these negotiations would remain confidential until the outcome was known.

Dr. SEGAL asked to be assured that if an interim report was received it would first be circulated to M.P.s rather than be issued for private circulation among 55,000 qualified members of the medical profession.

Mr. BEVAN said the negotiations were with the profession about the conditions under which they proposed to serve in a national service. They did not directly concern M.P.s. The matter was essentially one for the medical profession in the first instance and afterwards for the House of Commons if it wished.

EPIDEMIOLOGICAL NOTES

Food-poisoning at Birkenhead

Over a hundred people at five different parties in the Birkenhead and Wirral area were taken suddenly ill in the course of Saturday, June 28. All required treatment, and 72 were admitted to three hospitals. Except for a few cases all were discharged to their homes on the following day.

It was soon clear that the only item of food common to the four wedding parties and a child's birthday party was a large trifle. At one party 5 people in a group of 6 ate the trifle and were affected; the only one who did not eat the trifle was not affected. Further investigation showed that a woman and her child who ate the trifle after scraping off the cream which covered it were also affected. This suggested that it was the body of the trifle rather than the cream layer which was infected.

Bacteriological investigation revealed *Staph. aureus* as the organism probably responsible. It was recovered from the patients, from the trifle, and from a sty on the eye of one of the employees who prepared the trifle. Typing has not yet been completed.

Discussion of Table

In *England and Wales* there was a fall in the notifications of most infectious diseases; the decreases included measles 2,739, acute pneumonia 87, and cerebrospinal fever 14, and the only increase of any size was scarlet fever 103.

A small rise in the incidence of scarlet fever was recorded throughout the country; the largest increase was Glamorgan-shire 27. No change occurred in the local trends of diphtheria. The only variations in the returns for whooping-cough were an increase in London 31, and a decrease in Surrey 46.

There were large decreases in the notifications of measles in many areas; the largest falls were Essex 332, Lancashire 265, Yorkshire West Riding 261, London 166, Derbyshire 147, Southampton 137, Lincolnshire 130, Middlesex 124, and Surrey 111.

Of the 12 cases of paratyphoid fever, 10 were notified in Durham (Gateshead C.B. 4, Blaydon U.D. 5, Stanley U.D. 1). A new outbreak of dysentery in Berkshire involved 18 persons (Abingdon M.B. 11, Abingdon R.D. 6, and Hungerford R.D. 1).

In *Scotland* there was a decrease in the notifications of acute primary pneumonia 92, whooping-cough 37, scarlet fever 30, and diphtheria 8. Of the 39 cases of dysentery 19 were notified in Edinburgh.

In *Eire* a rise occurred in the incidence of diarrhoea and enteritis 29 and of measles 17. These rises were mainly due to the experience of Dublin C.B.

In *Northern Ireland* only slight changes were reported in the incidence of infectious diseases.

Week Ending June 21

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 870, whooping-cough 2,107, diphtheria 220, measles 10,632, acute pneumonia 328, cerebrospinal fever 39, acute poliomyelitis 44, dysentery 47, smallpox 7, paratyphoid 11, typhoid 7.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 14.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Medical News

The Lister Institute

The report of the Governing Body of the Lister Institute of Preventive Medicine, which has just been published, records that the Council has re-elected to the Governing Body as its representatives Prof. H. R. Dean, F.R.C.P., Sir Paul Fildes, F.R.S., and Sir Henry Dale, F.R.S. Research units housed at the Institute are the Bacterial Chemistry Unit, the National Collection of Type Cultures, and the Blood Group Research Unit, all of the Medical Research Council, and the Blood Group Reference Laboratory of the Ministry of Health. A survey of the scientific work carried out during the year refers to Mr. Standfast's examination of the characteristics of *H. pertussis* to discover whether the organism undergoes dissociation due to inherent or environmental factors and whether these influence the potency of vaccines. Miss Spooner, studying the reactive substances found in transfusion material, has been concentrating chiefly on the liberation of histamine and adenosine from the perfused lung when such substances are given intravenously; and she and Dr. M. G. Macfarlane have been investigating the chemical changes in muscles during and after ischaemia. The results suggest that the changes leading to clinical shock after the release of a tourniquet may arise from the failure to re-establish the cycle of carbohydrate metabolism. Dr. Duthie, working with organisms of the subtilis group, has shown that the maximum production of penicillinase is obtained only when penicillin is added continuously during the growth phase of the bacteria, and he is investigating the possibility of producing an antiserum against staphylococcal penicillinase. Drs. Mackay and Kekwick have developed a procedure (suitable for large-scale production) for separating immune globulins from human plasma. Preliminary tests by the Medical Research Council indicate that the product is prophylactic against measles. Investigations into nicotinamide are being continued by Dr. Ellinger and his colleagues, who have published two papers in this *Journal* (Oct. 26, 1946, p. 611, and May 17, 1947, p. 672).

Ex-Service Nursing Orderlies

Correspondents in our columns have recently debated whether Service-trained nursing orderlies should be admitted as State registered nurses without obtaining civilian qualifications, with a view to mitigating the shortage of nurses. The Department of Health for Scotland now announces that opportunity will be given for ex-Service men and women nursing orderlies with first-class qualifications to become State registered nurses after an intensive course of one year's duration instead of the normal three years'. The General Nursing Council for Scotland will allow ex-Service men and women to sit for the examinations if they were Class I nursing orderlies, or the equivalent, in the Forces and had two years' experience of nursing under a State registered nurse. Three such courses have started at Stracathro Hospital, Angus, the Law Junction Hospital, Lanarkshire, and Ballochmyle Hospital, Ayrshire; a fourth is being planned. Temporary nursing employment before the opening of the course will be found for those who want it. Men and women in the Forces should apply through Service channels; those who have been demobilized should write to the Chief Nursing Officer, Department of Health for Scotland, St. Andrew's House, Edinburgh.

Buckston Browne Prize

The council of the Harveian Society of London has selected "The Mental and Physical Effects of Pain" as the subject for the next Buckston Browne Prize essay. The prize, consisting of a medal and £100, will be awarded for the best essay on the above subject and is open to any member of the medical profession, under 45 years of age, registered in the British Isles or the Dominions. Essays must be submitted by Oct. 1, 1948. Further particulars may be obtained from Sir Cecil Wakeley, K.B.E., C.B., D.Sc., F.R.C.S., 14, Devonshire Street, Portland Place, London, W.1.

B.C.G. in Norway

At a meeting of the Tuberculosis Association of Norwegian Doctors, a resolution, unanimously adopted, included this statement: "The Tuberculosis Association of Norwegian Doctors recommends to the Department for Social Affairs the promotion of proposals for a law dealing with general B.C.G. vaccination of school-children of the national schools at school-leaving age, army recruits, and other young people, as well as of other population groups which are particularly exposed to infection with tuberculosis."

Exhibition at the Bodleian

An exhibition of books and manuscripts on medicine, surgery, and physiology has been opened at the Bodleian Library, Oxford (admission free). An illustrated catalogue (price 1s.) is available. The manuscripts include works by Hippocrates, Galen, Isaac Judaeus, Albucasis, and Avicenna.

R.S.M. Awards and Elections

Sir Alexander Fleming and Sir Howard Florey were jointly awarded the Gold Medal of the Royal Society of Medicine on July 1. Prof. R. R. Macintosh was awarded the Hickman Medal in Anaesthesia. At the same meeting the following were elected Honorary Fellows: Sir Edward Mellanby, Dr. C. M. Wenyon, Prof. Naguib Mahfouz Pacha, of Cairo, and Prof. Einar Key, of Sweden. The following Officers were elected for the session 1947-8: president, Sir Maurice Cassidy; immediate past president, Sir Gordon Gordon-Taylor; hon. secretaries, Mr. W. A. Pool and Dr. A. T. M. Wilson; hon. treasurers, Dr. Charles Newman and Mr. L. R. Broster; hon. librarians, Mr. E. K. Martin and Dr. Thomas Hunt; hon. editors, Mr. Eric A. Crook and Dr. E. R. Cullinan.

Visit of Czech Pathologist

Prof. Herman Siki, Director of the Department of Morbid Anatomy at the University of Prague, is visiting this country under the auspices of the British Council, and delivered a lecture on "Lesser Known Histological Methods for Routine Use in the Laboratory" at the meeting of the Association of Clinical Pathologists at Cambridge on June 27. He is attending the meeting of the Pathological Society at Newcastle on July 4-5 and will then return to London.

Discoverers of Paludrine Honoured

Drs. F. H. S. Curd, D. G. Davey, and F. L. Rose were presented with the Gold Medal in Therapeutics of the Society of Apothecaries on June 17 at the Apothecaries' Hall by the Master of the Company Dr. C. Thackray Parsons, for the joint research which culminated in the discovery of paludrine. Dr. Davey has also been awarded the Chalmers Medal by the Royal Society of Tropical Medicine and Hygiene. At the age of 34 he is the youngest recipient of this medal.

For Discovery of BAL

Prof. Rudolph Peters, M.C., F.R.S., who produced BAL early in the recent war, has been presented with the United States Medal of Freedom and Silver Palm.

COMING EVENTS

Royal Medico-Psychological Association

The 106th annual meeting of the Royal Medico-Psychological Association will be held in the Winter Garden Lecture Hall, Eastbourne, on Wednesday, Thursday, and Friday, July 9, 10, and 11, under the presidency of Dr. W. Gordon Masefield. The proceedings will open with the annual general meeting on July 9, at 11 a.m., when the officers for 1947-8 will be elected and other business transacted. At 2.30 p.m., Dr. Masefield will be inducted to the office of president and will deliver an address, and at 7.30 p.m. for 8 p.m., the annual dinner will be held at the Gran Hotel. On July 10, at 10.15 a.m., Dr. Geoffrey Evans and Dr. Noel Harris will present papers on "The Place of Psychiatry in Medicine," and at 2.15 p.m. there will be papers by Dr. Donald Stewart on "The Relation of Society to Occupational Health," and by Dr. John Thwaites on "Psychiatry in Relation to General Practice." On July 11, at 10.15 a.m., a paper by Mr. F. C. Webster, Architect to the Board of Control, and Dr. J. J. O'Reill on "The Planning of Modern Psychiatric Units," will be presented and at 2 p.m. the Child Psychiatry Section will meet at Public Health House, The Avenue, Eastbourne.

Urology

The seventh congress of the International Society of Urology will be held at St. Moritz, Switzerland, from Aug. 25 to 28, with the following programme which shows in parentheses the names of the British contributors to the discussions. Aug. 25, "The Aetiology of Primary Renal Calculus" (Mr. H. P. Winsbury-White). Aug. 26, "The Diagnosis and Treatment of Renal Tuberculosis" (Mr. Hamilton Bailey, Dr. Cuthbert Dukes, Mr. David Band). "Transplantation of the Ureter" (Mr. Arthur Jacobs). Aug. 27, general excursion and meeting. Aug. 28, "The Use of Sulphonamides and Penicillin in Urology" (Mr. J. G. Yates and Mr. Clifford Morson); "Hormone Therapy in Cancer of the Prostate" (Mr. Clifford Morson, Mr. Hamilton Bailey). Aug. 29 there will be excursions to sanatoria. Further particulars of the congress may be obtained from Mr. Clifford Morson, O.B.E. F.R.C.S., 86, Brook Street, London, W.1.

Abernethian Society

Prof. John Fulton, Sterling Professor of Physiology in the University of Yale, will deliver an address on "Harvey Cushing and His Books" before the Abernethian Society in the Clinical Lecture Theatre of St. Bartholomew's Hospital, London, E.C., on Thursday, July 10, at 5.30 p.m.

Presentation of Prizes

Sir Frederick Ogilvie will present the prizes in the library of the London Hospital Medical College on Wednesday, July 9, at 3 p.m.

Pure and Applied Chemistry

The eleventh International Congress of Pure and Applied Chemistry, which the war prevented from being held in 1941, will be held in London on July 16-24, in conjunction with the also postponed Centenary Celebrations of the Chemical Society. Lord Overhulme will preside. Further information may be obtained from the Hon. Organizer, the 11th International Congress of Pure and Applied Chemistry, 56, Victoria Street, London, S.W.1.

Medical Hydrology

The annual meeting of the International Society of Medical Hydrology will be held at Rheinfelden, Switzerland, from Sept. 11 to 15, with the following programme: Sept. 11, first medical discussion, "Spa and Climatic Treatment for Children"; Sept. 12, papers on "Peripheral Vascular Disorder," followed by "Balneotherapy in Non-rheumatic Diseases," at Schinznach Bad; Sept. 13, "Spa treatment in Rehabilitation after Accidents and War Injuries," to be held at Baden; Sept. 14, Further papers, at Basle; Sept. 15, beginning of excursion through the Engadine, due to last eight days, with a supplemental three days in the Bernese Oberland, if so wished. Further details may be obtained from the honorary secretary, International Society of Medical Hydrology, 28, The Circus, Bath, England.

SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Tuesday, July 8, 6.15 p.m. Moynihan Lecture by Dr. W. K. Livingston (Professor of Surgery in the University of Oregon): Physiological Responses to Wounding. Thursday, July 10, 6.15 p.m. Hunterian Lecture by Prof. H. Jackson: Role of Anatomy in Symptomatology of Lumbar Disk Protrusions.

POSTGRADUATE DIARY

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, W.C.—Tuesday, July 8, 5 p.m. Mr. V. E. Negus: The Nose, Nasopharynx, and Paranasal Sinuses.

APPOINTMENTS

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—Honorary Assistant *gynecologic* Surgeons, H. H. Fouracre Barns, F.R.C.S., M.R.C.O.G., B. G. Cers, F.R.C.S.Ed., M.R.C.O.G.

LONDON COUNTY COUNCIL.—The following appointments in the Council's vital health services are announced at the hospitals indicated in parentheses: *Assistant Medical Officers*, J. Aminoff, M.R.C.S., L.R.C.P. (Friern); M. W. near, M.R.C.S., L.R.C.P. (Cane Hill); P. R. A. May, M.B., B.Chir. (Kiley); R. M. Jones, M.B., B.S. (Long Grove).

LOUIS, F., F.R.C.S., Accident and Orthopaedic Surgeon, St. Margaret's Hospital and Great Western Hospital, Swindon.

BIRTHS, MARRIAGES, AND DEATHS

Charge for an insertion under this head is 10s. 6d. for 18 words or less, 1s. 6d. for each six or less. Payment should be forwarded with notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday evening.

BIRTHS

NES.—On June 22, 1947, at St. Anne's Nursing Home, Nottingham, to Edith (née Flinn), wife of Dr. H. G. Barnes, a daughter.

TCHER.—On June 23, 1947, at Cherisey Hill Nursing Home, Carlisle, to Edith, wife of Tom Fletcher, M.D., F.R.C.S., of Papcastle, Cockermouth, a son and brother for Gair and Nigel.

FEITH.—On June 22, 1947, at the North Oxford Nursing Home, Oxford, to Lucie, wife of Dr. R. C. L. Griffiths, of Newport Pagnell, a daughter.

E.—On June 22, 1947, at Newcastle-on-Tyne, to Marie Barbara (née Ivey), wife of Dr. Leonard H. Lake, of 79, Holly Avenue, Jesmond, Newcastle-on-Tyne, 2, a daughter—Janet Havelock.

LAREN.—On June 4, 1947, at Fernbrae Nursing Home, Dundee, to Pat (née Taylor), wife of Flt.-Lt. Bill McLaren, R.A.F., a son—Andrew Hood.

MARRIAGE

WFORO—SETON.—On June 18, 1947, at Kilmarnock, Ayrshire, W. Cowan Crawford, L.R.C.S., L.R.C.P., to Mary Stewart Seton, S.R.N.

DEATHS

YNALL.—On June 26, 1947, at Riversdale, Fielden Park, West Didsbury, Manchester, Charles Philip Brentnall, M.C., F.R.C.O.G., Honorary Surgeon to Mary's Hospitals, Manchester, aged 56 years. The very dearly loved husband of Muriel Young Brentnall.

BLAY.—On June 14, 1947, at Amarah, Lower Bourne, Farnham, Surrey, Leonard Findlay, M.D., D.Sc., F.R.C.P., in his 70th year. Funeral private. American and Canadian papers please copy.

PHILIS.—On June 17, 1947, at Bath, Francis Howard, Companion Order of St. John, Chevalier Order of Leopold I, M.D., F.R.C.P., M.R.C.S., R.C.P., D.M.R.E., L.M., formerly of 4, Stanhope Gate, Park Lane, London.

ATT.—On May 31, 1947, in Gloucester, Havelock Thos. Lippiatt, M.C., D.McGill, F.R.C.S.Ed.

E.—On June 22, 1947, at 60, Kewstoke Road, Bristol 9, Ethel, wife of John de Coverly Veale.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Stammering

Q.—A boy aged 10 stammers badly. He started stammering at the age of 4 after removal of tonsils and adenoids. He is not a mouth-breather, and had training by an elocutionist for about a year without improvement. He is very intelligent and good at studies and games. Will you kindly discuss in detail the examination and treatment, as stammering is not discussed in most textbooks?

A.—First, any remediable physical disorders should be attended to, particularly if they are in the ear, nose, or throat area. These latter troubles do not cause stammering but they may delay the patient's recovery. Then it is essential in a young child to determine by observation which hand Nature intended him to use for his most skilled actions, and to see to it that he writes with that hand, whether left or right. Do not attempt corrective training; there is no justification whatever for forcing him to conform with the majority. If, however, the habit of writing with the non-dominant hand has been well established, any change may cause too great an upheaval. Speaking generally, the reversal can be made without serious disturbance if the child is less than 12 years old, provided that he is blessed with reasonable educators.

The next step is to induce all those coming into contact with him—and particularly parents and school-teachers—to refrain from treating the child's stammer and to ignore it so far as is possible. The teaching of elocution is likely to make many stammerers worse and it is doubtful if it is ever a help. Speech treatment can be carried out satisfactorily only by qualified speech therapists, who now form a recognized branch of medical auxiliaries and undergo a three-years training and after their final examination receive a standard diploma. The family doctor rarely has the knowledge and never the time necessary to treat this disorder. The speech treatment consists in a fairly complete re-education of the whole speech process, beginning with a "detensing" of the patient by instruction in complete bodily—and if possible mental—relaxation. Further treatment varies with the case and is too technical and detailed to outline here. In every case, however, a psychiatric survey should be made to ensure that serious psychological factors are not perpetuating the stammer. When present their treatment should be attempted at the same time as that of the speech itself. A brief outline of the problem of stammering will be found in the *Survey of Child Psychiatry*, edited by R. G. Gordon and published by the Oxford University Press.

Psychology of Make-believe

Q.—Children between the ages of 2 and 5 are prone to pretend they are other children. My son, nearly 3, occasionally insists that he is his cousin, and that his name is Bobby and not David. He also pretends that his parents are his aunt and uncle respectively—Bobby's parents. Can this be explained by a psychologist; and is it wise to encourage this play-acting? In all other respects the child is normal and plays with friends of his own age.

A.—Young children who pretend that they are other people have a way of solving their difficulties by this means. Sometimes it is obvious how this is done; for example, when a child has an imaginary companion whom he invests with all his "naughty" characteristics, so escaping the uncomfortable sense of guilt which he would otherwise experience. In the same way it may be useful to have an extra imaginary set of parents, for children are often afraid that their angry wishes may do harm to the parents whom they love, and so they invent "whipping-boys" of various sorts. Certainly such make-believe is no sign of abnormality but a natural defence mechanism making for mental health.

Fat Injections for Scars

Q.—*Can you give me any information as to the use of injections of fat for the removal of unsightly scars?*

A.—Injection of fat for the improvement of depressed scars is commonly used by quacks. The result is not impressive. The fat is usually absorbed or becomes a hard fibrous mass which can be felt or seen beneath the scar. The result is rarely as good as that obtained by careful excision and resuture, attention being paid to the contour and light-catching properties of the scar by building up subcutaneous tissue to secure a smooth surface.

Fissured Lip

Q.—*A patient has suffered from a fissured lip at the angle of the mouth for six months. It heals for a few days but quickly breaks down. Lip salves and collodion have been tried without success. There is no oral sepsis (complete dentures), and the general health is good. Can you suggest a cure?*

A.—Fissures at the angle of the mouth which are infected may sometimes be induced to heal by the local use of penicillin. In intractable cases, however, where the fissure keeps breaking down, the only cure often is to excise the fissure and to suture, keeping the sutures in place for longer than the normal period to ensure that stretching of the mouth will not cause breakdown in the area before complete healing has taken place.

Increasing the Size of the Breasts

Q.—*A "show-girl" is anxious to increase her breast measurements; small doses of oestrogen and progesterone have no effect. Is this a safe treatment and is it likely to be effective? If so, what dosage should be given and at what intervals? There is a history of salpingectomy in 1932 when she was 19; both ovaries were left in situ. Would this influence the effect of the treatment?*

A.—It is usually possible to produce breast enlargement with oestrogens, providing the breast tissue is inherently capable of response and an adequate dose is given. The effect might be enhanced by giving progesterone in combination with oestrogen, but progesterone alone is unlikely to be of value. However, oestrogen therapy, either local or systemic, is not advised because its effect is temporary and when it is withdrawn the breasts not only return to their former size but tend to be less firm and shapely. The changes are rather like those occurring in pregnancy, including darkening of the areola and increased vascularity; afterwards the breasts assume the appearance of those of a multipara. Moreover, the increased size cannot be maintained by giving oestrogens for an indefinite period because ill effects, such as menstrual disturbances, endometrial hyperplasia, pituitary and ovarian depression, and breast changes similar to those of "chronic mastitis," may occur. As an alternative to hormones, physiotherapy should be tried, especially arm exercises to develop the pectoral muscles and increase the blood supply to the breasts. Swimming might be particularly effective. The advantage of this type of treatment is that it can be continued regularly for an indefinite period. Salpingectomy does not affect the breasts.

Scabies Infection of Anus

Q.—*Have scabies mites been noted in the rectum or urine? Inquiries show that most cases of infection in Natal are due to natives sleeping in sacking, and that the parasite is often found around the anus.*

A.—The scabies mite has only been found living in the horny layer of the skin and never in the internal organs. Very occasional dead and partly macerated specimens have been demonstrated in the urine and sputum, but this was almost certainly due to contamination. It would be interesting to know just what the questioner means when he states that "inquiries" reveal that infections with scabies in Natal are usually due to natives sleeping in sacking. All other investigators have shown that, while an occasional infection from fomites may occur, transmission is due in the majority of cases to personal contact. Coarse material like sacking would be most unlikely to harbour *Sarcoptes* in any numbers. Was the alleged heavy infection with parasites round the anus confirmed by finding the mites

themselves? Other investigators have found that, while impetiginous lesions are common in the buttocks, a comparatively small number of mites occur in this region, while much larger numbers, giving rise to few clinical symptoms, are seen on the hands and wrists.

Renal Function Tests

Q.—*Is it possible to correlate specific renal function tests with specific renal lesions; for example, the water concentration test with damage to the tubules?*

A.—Although renal function tests are helpful in assessing the state of the kidneys, our knowledge of renal function is not yet sufficient to allow of our correlating specific renal function tests with specific renal lesions. Too many imponderables exist to make this possible. Theoretically it would seem that the water concentration test would throw light on the state of the kidneys, but too much weight should not be attached to the findings. It is quite possible that, with an increase of knowledge of the physiology of the kidneys, what is now theoretical may become practical.

First Pregnancy after Nephrectomy

Q.—*A patient, aged 40, just married, is anxious to have a child. She had one kidney removed at an early age. What are the hazards of a first pregnancy under these conditions?*

A.—Although many women with only one kidney go through pregnancy without suffering any ill effect, the combination of conditions must always give rise to some anxiety because the safety margin is small. The outlook in any case depends to some extent on the indication for the nephrectomy, and especially on the health and efficiency of the remaining kidney. Before advising this woman, renal function tests and also pyelography should be carried out. If the results are satisfactory the patient should be told that in the event of her becoming pregnant she will require careful supervision. The chief risks are pyelitis and any sort of toxæmia, and if these occur and do not respond immediately to conservative measures the pregnancy should be terminated.

Hormones and Carcinoma of Prostate

Q.—*Is there any proof that testosterone has converted a benign growth of the prostate into a malignant one? In view of the fact that stilboestrol causes regression the possibility seems obvious.*

A.—There is no proof or indication, either clinical or experimental. The inhibitory action of stilboestrol on carcinoma of the prostate does perhaps raise the possibility, as do also the hypertrophy and hyperplasia of the prostatic epithelium which result from testosterone administration under certain conditions. However, apart from the absence of objective direct evidence, it is recognized that there is a malignant neoplastic stimulus (of uncertain character), as well as a hormone stimulus, involved in the induction of carcinoma of the prostate. Thus Huggins found that even when bilateral adrenalectomy was superimposed on bilateral orchidectomy, so that all androgenic stimulation was eliminated, a relapse from carcinoma of the prostate could not be halted indefinitely.

Urinary Incontinence

Q.—*A male aged 34 complains of urinary incontinence, which started four years ago. The condition was first noticed at night and has become progressively worse. Examination of urine, urinary tract, and bladder has proved negative. Belladonna and ergot pills have been of help; is there any danger in their prolonged administration? What further treatment and investigations do you advise?*

A.—The diagnosis in this case is obscure and little can be said about treatment until it has been elucidated. The symptoms might fit in with a prostatic lesion, but the patient's age makes the presence of an ordinary enlargement extremely improbable. It is possible, however, that he has what the American urologists call a "prostatic bar": this is generally missed by the inexperienced cystoscopist. It is important to know whether there is any residual urine, and a catheter should be passed after he has made every effort to empty his bladder.

It is quite likely that residual urine will be found and that this accounts for the lack of control. A small perurethral resection would then probably bring about great improvement. It is to be assumed that the possibility of a lesion of the central nervous system has been eliminated. In this case the incontinence first became marked by night, and it is unlikely, therefore, that it is functional. There is no objection to continuing the only treatment which so far has been effective.

Acute Rheumatism and the Heart

Q.—Cases have been reported in America of cardiac damage following acute rheumatism treated by salicylates. I understand that rheumatic fever in an adult does not cause permanent cardiac damage provided the heart was previously healthy. At what age can it be assumed that rheumatic fever is unlikely to inflict permanent damage on the heart?

A.—Cardiac involvement probably occurs in every case of acute rheumatic fever or acute rheumatism, and this may lead to permanent cardiac damage. Neither the incidence of cardiac involvement nor the tendency to permanent damage appears to be influenced by the administration of salicylates in any form. First attacks of rheumatic fever are less likely to inflict permanent damage in subjects over 15, and in subjects over 20 the risk is slight. However, any prognostic assessment on these grounds is unwarranted unless the full clinical picture is borne in mind. In addition, it would be unwise to assume that the benign course of adult cases will be an unchanging feature of the disease for all time.

Wassermann Reaction of Cadaver Blood

Q.—On admission to hospital a patient's Wassermann reaction was negative. At the subsequent necropsy a Wassermann test done on blood taken from the body gave a positive reaction. This result was held to be valueless, as blood from a cadaver is always Wassermann positive. If this is correct, what is the explanation?

A.—Cadaver blood occasionally, but not invariably, gives a false positive Wassermann reaction; not uncommonly serum obtained from a corpse is anticomplementary. There is no satisfactory explanation of either phenomenon. In view of the fact that the reaction was negative during life and positive after death, it should be borne in mind that a considerable proportion of false positive results of Wassermann tests done in this country are due to faulty technique or inexperience.

Sulphonamides and Mepacrine

Q.—What are the incompatibilities of the sulphonamides and of mepacrine when administered by the oral route? Do these drugs damage the liver? Can they be given together without fear of incompatibility or liver damage? If not, how can these risks be overcome?

A.—Para-aminobenzoic acid should not be given with sulphonamide drugs because of therapeutic interference, and it is advised that saline purges, thiopentone, phenazonum, amidopyrine, phenylhydrazine, gold, and arsenical compounds be avoided when sulphonamides are being given. Some recommend that pamaquin should not be given with mepacrine. In practice, however, there are few serious incompatibilities of sulphonamide drugs or mepacrine given orally. In therapeutic dosage their damaging effect on the liver is negligible. Sulphapyridine and mepacrine may be given together.

Eclampsia a Toxaemia?

Q.—What evidence is there for the toxaemia theory of eclampsia? Have samples of systemic or portal blood from such cases ever been given to other individuals, or to experimental animals, with the production of significant symptoms?

A.—The view that eclampsia is a manifestation of a toxaemia was elaborated during the late nineteenth and early twentieth centuries. It was based on observations such as the following: regenerative changes in various organs, especially liver and kidney, were rather similar to those produced by chemical poisons; the wide distribution of lesions suggested that the causal agent was in the circulation; the occasional finding of

what were considered similar lesions in the foetus was also thought to favour the idea of a toxin which had crossed the placenta; the organ most constantly found to be damaged was the liver. Nevertheless, a toxin has never been demonstrated and, if there is one, its origin remains unknown. Systemic blood, serum, urine, and extracts of placentae from eclamptic women have been injected into various laboratory animals, and numerous experiments of this kind are reviewed by J. Whitridge Williams in *Obstetrics*, 4th edition, 1920. What were at first thought to be significant effects in the animals were later shown to be serum and foreign-protein reactions. Further and better-controlled experiments of this kind did not provide evidence of the presence of any special toxin. Systemic blood from women suffering from eclampsia has also been transfused into women suffering from haemorrhage, without producing any special symptoms. J. B. deLee in the 4th edition of *The Principles and Practice of Obstetrics* mentions that Bumm carried out work of this kind in 1922.

NOTES AND COMMENTS

Leuconychia.—Dr. ALICE E. B. HARDING (London, S.W.) writes: Belatedly reading the *Journal* of May 17, I have seen the answer on leuconychia (p. 705) and find it unacceptable. Some years ago I noticed that though my finger nails are patterned to an unusual extent with transverse white marks, my toe nails show no linear deposits at all. I considered the question of exposure to light as one of the possible factors, and to test this theory I kept my finger nails painted with a deep-coloured nail varnish for three months. The varnish was removed as necessary with acetone and reapplied with the usual soft brush. The white markings gradually faded, and at the end of the three months had gone completely. During this time my cuticle toilet was carried out as usual each night. When I finally (and thankfully) discarded the varnish, many marks returned within a week; their number and size seem to vary with the general state of my health, and are greater during the winter than the summer, when, as is the case with every doctor, I am more apt to be "run down" and tired. It would seem that there is a constitutional factor concerned, but that the actual deposition is determined by exposure to light.

"Susceptibility" to Lousiness.—Dr. K. M. TOMLINSON (Leamington Spa) writes: In your expert's reply (June 14, p. 871) upon the above subject he postulates that those people who consider themselves more susceptible to flea bites are the more sensitive by nature and therefore more likely to notice bites. In Southern California in the dry season flea bites cause considerable and widespread distress to susceptible patients. Howard Eder reports that all susceptible patients treated with large doses of thiamine hydrochloride (he used 10 mg. three times a day to begin with, and then a maintenance dose of 10 mg. daily) obtained relief while so saturated. On desaturation he noted that their susceptibility returned, but relief was again obtained on further treatment. It was my intention to try the effect of thiamine saturation on patients with other infestations, such as scabies, to note whether the irritation became less. This would infer a similar distaste for thiamine on behalf of the acarus. The timely warning of the toxicity of thiamine hydrochloride by Reingold, Haley, Fleseher, and others dissuaded me from experiment in such a relatively simple and easily cured ailment as scabies. It might, however, be worth while for any medical man who is markedly susceptible to fleas, mosquitoes, etc., to try the effect of thiamine hydrochloride on himself. Fortunately I am not a suitable guinea-pig.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 5 1947

REGIONAL HOSPITAL BOARDS

CHAIRMEN AND MEMBERS

In December last (*Journal*, Dec. 28, 1946, p. 1000) the Minister of Health defined the areas for which Regional Hospital Boards would be responsible under the National Health Service Act. On June 27 he published an order setting out the constitution of these Boards. The Boards will organize and develop the hospital and specialist services in their respective areas, though ultimate control will remain with the Minister. The Boards will later appoint Hospital Management Committees for the local administration of all hospitals except teaching hospitals. The chairmen have been appointed for a period ending March, 1950; one-third of the other members will retire at the end of each year beginning in March, 1949. They will be eligible for reappointment, and the term of office of future members will be three years. All the appointments are honorary. We list below the chairmen and members of the Boards.

Chairmen

Newcastle Area: Sir Walter Thompson (chairman of Newcastle-upon-Tyne C. B. Health Committee). Leeds Area: Mr. J. E. Fattorini (chairman of Bradford Infirmary). Sheffield Area: Sir Basil Gibson (formerly Town Clerk of Sheffield). East Anglian Area: Lord Cranbrook (councillor, E. Suffolk C.C.). N.W. Metropolitan Area: Mr. F. Messer, M.P. (chairman of Middlesex C.C.). N.E. Metropolitan Area: Mr. J. W. Bowen (formerly chairman of Mental Hospitals Committee of the London C.C.). S.E. Metropolitan Area: Mr. K. I. Julian (chairman of Royal Sussex Hospital, Brighton). S.W. Metropolitan Area: Mr. F. H. Elliott (chairman of Surrey C.C. Public Health Committee). Oxford Area: Dr. A. Q. Wells (chairman of the Oxon C.C. Public Health Committee). South-western Area: Mr. H. G. Tanner (treasurer, University of Bristol). Welsh Area: Sir Frederick J. Alban (secretary and comptroller of the Welsh National Memorial Association). Birmingham Area: Mr. R. R. Adam (chairman of the Worcester C.C. Public Health Committee). Manchester Area: Sir John Stopford (Vice-chancellor of the University of Manchester). Liverpool Area: Mr. T. Keeling (chairman of the Management Committee of the Royal Southern Hospital).

Members

Newcastle Regional Hospital Area.—Mr. E. F. Collingwood, C.B.E., J.P.; Mr. D. C. Dickson, F.R.C.S.Ed.; Dr. T. H. Baies; Dr. W. Fraser; Ald. A. Cooper; Mr. T. Benfold, C.B.E., J.P.; Mr. T. A. Wright; Mr. J. A. Hutchison; Mr. J. Foster; Mr. R. Muckle; Lord Eustace Percy; Prof. R. B. Green (Dean and Professor of Anatomy, University of Durham); Prof. W. E. Hume, C.M.G. (late Professor of Medicine, University of Durham); Dr. J. R. Murray; Mr. W. Waddell; Mr. T. C. Squance, O.B.E.; Dr. J. R. Gibson (Viscountess Ridley; Lord Westwood, O.B.E.; Miss D. R. Gibson (Matron, General Hospital, Newcastle); Prof. F. J. Nairass (Professor of Medicine, University of Durham); Dr. G. P. Milne, M.R.C.O.G.; Dr. R. E. Jowett; Ald. J. Cohen, J.P.; Ald. A. J. Best, J.P.; Ald. P. S. Hancock, O.B.E.; Mr. G. D. Cochrane, J.P.; Mr. J. Oliver; Mr. T. B. Harston; Mr. L. Bird, M.B.E.

Leeds Regional Hospital Area.—Prof. M. J. Stewart (Professor of Pathology, Dean of Medical Faculty, University of Leeds); Dr. D. C. Muir; Dr. W. S. MacAdam; Ald. L. Chambers; Ald. A. Sugden, J.P.; Mr. L. Crowther, O.B.E., J.P.; Ald. H. J. Bambridge, O.B.E., J.P.; Miss M. F. Dykes (Matron, St. James's Hospital, Leeds); Prof. A. M. Claye (Professor of Obstetrics, University of Leeds); Mr. G. W. Black, F.R.C.S.; Dr. J. L. Russell; Ald. D. Bevers, J.P.; Mr. H. Denham; Mr. W. L. Lawton; Mr. B. Hazell, M.B.E.; Prof. R. E. Tunbridge, O.B.E. (Professor of Medicine, University of Leeds); Dr. W. S. Macdonald, M.C., J.P.; Mr. D. Watson, F.R.C.S.; Ald. R. E. Smith; Mr. A. Walker; Miss I. B. Shaw; Mr. S. C. Fryers; Mr. J. C. Hunter.

Sheffield Regional Hospital Area.—Prof. E. J. Wayne (Professor of Pharmacology and Therapeutics, University of Sheffield); Dr. J. W. Brown; Mr. A. W. Harrison; Ald. E. Sheerien; Mr. C. K. Hobson; Lord Quibell; Ald. C. F. Bowmer; Ald. H. Deer, J.P.; Mrs. F. J. Everard; Miss A. Wetherell; Prof. G. L. Roberts (Professor of Dental Surgery, University of Sheffield); Miss M. G. Bott, F.R.C.O.G.; Dr. K. K. Drury, M.C.; Dr. J. P. W. Jamie, M.C.; Ald. R. Shaw, J.P.; Ald. W. E. Yorke, J.P.; Mr. A. R. Martin; Mr. T. Pearson; Mr. E. W. Score, O.B.E.; Mr. R. E. Dewberry; Mr. J. L. A. Grout, M.C., F.R.C.S.; Mr. E. F. Finch, F.R.C.S.; Dr. A. B. Slack, M.C.; Ald. W. Bayliss, J.P.; Mrs. G. Buxton, J.P.; Mr. G. H. Round, J.P.; Mr. H. Ford; Mr. W. B. Jarvis; Lieut.-Col. N. G. Pearson, D.S.O., M.C.; Mr. M. Brown.

South-east Metropolitan Regional Hospital Area.—Mr. S. J. Worsley, D.S.O., M.C.; Mr. J. R. H. Turton, F.R.C.S.; Dr. H. A. Treble; Dame B. Lambert, D.B.E.; Mr. F. W. Chambers, O.B.E.; Ald. R. H. Burslem; Rev. H. Samuel; Ald. T. E. Morris; Dr. E. R. Boland, C.B.E. (Dean, Guy's Hospital Medical School); Mr. F. E. Feilden, F.R.C.S.Ed.; Dr. A. T. Rogers; Ald. Miss A. Hudson, M.B.E.; Lord Cunliffe; Mr. E. C. Sherwood; Miss E. K. N. Cumming; Mr. J. B. Hunter, C.B.E., M.C., F.R.C.S. (Dean of Faculty of Medicine, University of London); Dr. W. G. Masfield; Mr. C. W. Brook; The Hon. R. B. Buckley; Mr. W. Kelsey Fry, C.B.E., M.C., L.D.S.; Mr. W. C. H. Luskett; The Hon. Mrs S. L. Henley; Ald. S. C. C. Harris.

South-west Metropolitan Regional Hospital Area.—Mr. P. H. Michener, C.B., C.B.E., F.R.C.S.; Mr. J. M. Wyatt, F.R.C.S.; Mr. N. E. Waterfield, F.R.C.S.; Ald. A. E. Allaway; Ald. Col. C. H. Gibson; Sir Arthur Watson, C.B.E.; Ald. F. J. Wooley; Mr. J. A. Tulk; Miss E. C. Batho; Mr. M. F. Nichols, C.B.E., F.R.C.S. (Dean, St. George's Hospital Medical School, London); Dr. D. Curran; Dr. C. B. S. Fuller, M.C.; Ald. A. Lubbock; Mrs. H. Feiling; Mr. J. L. Williams; Miss P. Loc, M.B.E. (Matron, St. James's Mental Hospital); Mr. G. H. Macnab, F.R.C.S. (Dean, Westminster Hospital Medical School); Dr. D. Stark Murray; Mr. N. F. Adeney, F.R.C.S.; Mr. R. Sargood, M.P.; Mr. A. G. Linfield, O.B.E.; Mr. A. Hague-Winterbotham; Mr. E. F. Crundwell; Mr. G. E. Coke; Mr. G. Thompson.

Oxford Regional Hospital Area.—Prof. A. D. Gardner (Professor of Bacteriology, University of Oxford); Dr. J. S. I. Skottowe; Lord Henley; Mr. A. J. B. Selwood; Mr. E. C. Bevers; Mr. P. C. Rafferty; Ald. Mrs. A. Jenkins; Miss R. R. Jolliffe; Prof. A. W. M. Ellis (Regius Professor of Medicine, University of Oxford); Mr. J. A. Staffworthy, F.R.C.S.; Dr. D. S. Jones; Mr. A. R. Banham, F.R.C.S.; Miss R. Spooner; Col. C. B. Krabbe, O.B.E.; Rev. J. D. Turner; Prof. H. J. Seddon (Professor of Orthopaedic Surgery); Sir Oliver S. Franks, K.C.B.; Mr. A. Woodley; Mr. W. R. Robins; Mr. L. M. Paterson; Miss C. Adams; Dr. Janet Vaughan (Principal, Somerville College, Oxford).

East Anglian Regional Hospital Area.—Mr. T. S. Hele; Dr. R. Ellis; Dr. J. V. Morris; Ald. Mrs. M. Whitmore; Miss J. G. Thompson (Matron, E. Suffolk and Ipswich Hospital); Mr. P. F. Dennard; Mr. C. R. Caselton; Mrs. H. A. Adrian, J.P.; Mr. J. Granham; Mr. M. W. B. Bulman, F.R.C.S.; Dr. R. B. Fawkes, D.S.O., M.C.; Ald. S. Peel, J.P.; Ald. W. Brown; Ald. J. Brooksbank, J.P.; Mr. E. W. Plumpion, J.P.; Canon J. D. Day; Mr. W. B. Gourlay, M.C.; Mr. R. W. Butler, F.R.C.S.; Mr. J. B. Coster, J.P.; Mrs. E. Binfield; Mr. R. H. Parker, M.C.; Mr. R. B. Keeffe; Sir Cecil Oakes; Mr. O. Chivers; Mr. W. H. York.

North-west Metropolitan Regional Hospital Area.—Dr. H. E. A. Boldero (Dean, Middlesex Hospital Medical School); Dr. H. Joulès (Medical Superintendent, Central Middlesex County Hospital); Mr. A. C. Morson, O.B.E., F.R.C.S.; Mrs. F. M. Baker, C.B.E.; Ald. Mrs. Martin-Smith, M.B.E.; Col. The Hon. J. J. Astor; Mr. H. Fletcher; Miss V. Dart; Dr. H. W. C. Vines (Dean, Charing Cross Medical School); Dr. S. J. Cowell (Vice-Dean, University College Hospital Medical School); Dr. J. R. Rees, C.B.E.; Mr. A. S. Gough, F.R.C.S.; Miss E. Rickards; Mrs. F. M. Suggate; Sir Owen Morshead, K.C.V.O., D.S.O., M.C.; Mr. H. Lesser

O.B.E.; Prof. J. M. Mackintosh (Professor of Public Health, London School of Hygiene); Miss E. Cockayne (Matron, Royal Free Hospital); Mr. G. B. Jeffery; Dr. K. G. Lloyd-Williams (Dean, London School of Medicine for Women); Dr. D. H. Brinton (Dean, St. Mary's Medical School); Mr. L. W. Plewes, F.R.C.S.; Mr. R. Stamp; Ald. H. R. Ncat; Sir A. H. Maxwell; Mr. A. G. de Rothschild; Dr. Stephen Taylor, M.P.; Mr. F. J. Ballard.

North-east Metropolitan Regional Hospital Area.—Mr. S. Hastings, M.P.; Ald. S. F. Johnson; Mr. E. T. Nethercoat, C.B.E.; Mr. C. S. B. Wentworth-Stanley; Mrs. H. M. Blair-Fish; Capt. H. Bricley, O.B.E., M.C.; Mr. C. C. Carus-Wilson, M.C.; Ald. C. E. S. Blackmore; Prof. S. P. Bedson (Professor of Bacteriology, London Hospital); Dr. R. Strom-Olsen; Dr. H. M. M. Mackay; Lieut.-Cmdr. H. Denton; Mr. L. Comyns, M.P.; Major R. P. Woodhouse; Dr. G. Graham; Mr. R. W. Reid, F.R.C.S.; Dr. R. Poots; Mrs. A. L. Hollingsworth; Mr. W. V. Wakefield; Mr. H. W. Butler, M.P.; Ald. C. H. Simmons.

South-western Regional Hospital Area.—Dr. S. McClements; Dr. R. E. Hemphill; Mr. J. W. G. H. Riddell, M.C., F.R.C.S.Ed.; Ald. J. J. Milton; Ald. W. Barrett; Ald. Mrs. J. M. Phillips; Mr. A. L. Candler; Mr. C. P. Brown; Mr. J. R. Makeig Jones; Miss R. C. Shackles (Matron, Royal United Hospital, Bath); Sir Philip Morris, C.B.E.; Dr. W. Niccol; Dr. C. T. Andrews; Col. H. B. Stokes, M.B.E.; Mrs. K. A. Goddard; Mr. P. E. Russell; Mr. E. Cadbury, D.S.C., D.F.C.; Brig. J. Morrison, M.B.E.; Mr. A. C. Bowden, L.D.S.; Prof. R. J. Broeklehurst (Professor of Physiology, University of Bristol); Prof. R. M. Walker (Professor of Surgery, University of Bristol); Dr. C. J. Fuller; Mr. S. C. Morland; Mrs. J. Marshall; Ald. H. G. Mason; Mrs. M. F. Williams; Mr. G. G. Gilmour-White, O.B.E.; Miss M. F. Awdry.

Welsh Regional Hospital Area.—Prof. E. A. Owen (Professor of Physics, University of Wales); Mr. R. D. Aiyar, F.R.C.S.Ed.; Mr. A. H. Coleman, O.B.E., F.R.C.S.Ed.; Dr. H. G. Davies; Ald. E. A. Cross, M.B.E.; Ald. R. Gronow; Rev. B. Waldo-Lewis; Mr. R. Davies; Mr. A. S. W. Johnson; Ald. T. J. Kerrigan; Mrs. E. Owen; Ald. J. Dicks; Prof. O. H. Williams (Emeritus Professor of Surgery, Liverpool University); Dr. D. H. Pennant, D.S.O.; Ald. W. C. Davies; Ald. J. J. Panes, O.B.E.; Mr. H. Alexander; Mr. T. P. Davies; Ald. W. Casey; Dr. I. J. Davies; Prof. R. M. F. Picken (Professor of Preventive Medicine, Acting Provost, University of Wales); Prof. T. B. Davie (Dean of Medical School, Liverpool University); Dr. J. H. O. Roberts; Mr. J. Li. Davies, O.B.E., F.R.C.S.Ed.; Ald. the Rev. W. D. Thomas; Mr. T. McDonald; Mr. W. J. Canton; Mrs. K. W. Jones-Roberts; Mr. W. Evans; Mr. H. T. Edwards; Ald. T. Evans.

Birmingham Regional Hospital Area.—Prof. Sir L. G. Parsons (Dean of Medical School, University of Birmingham); Prof. H. F. Humphreys, O.B.E., M.C. (Professor of Dental Surgery, University of Birmingham); Mr. N. Duggan, F.R.C.S.; Dr. J. J. O'Reilly; Mrs. A. L. Barker; Capt. L. H. Green, M.B.E.; Mr. A. Smith; Mr. W. T. Smith; Major O. Hotchkiss; Mr. H. S. Wailes; Dr. R. E. Priestley, M.C.; Mr. L. A. Dingley, F.R.C.S.; Dr. J. A. Brown; Mr. J. Latham; Sir E. J. Johnson; Mr. E. T. Hoble; Ald. L. Whitehouse; Miss Smalton; Mr. G. A. Thompson; Prof. A. P. Thomson, M.C. (Professor of Therapeutics, University of Birmingham); Dr. J. H. Sheldon; Mr. A. J. Watson, F.R.C.S.; Mr. D. J. Evans; Ald. A. F. Bradbeer; Ald. W. L. Dingley; Mr. V. W. Grosvenor; Mr. L. E. Bury; Mr. C. O. Langley.

Manchester Regional Hospital Area.—Dr. W. Briggs; Prof. D. Dougal (Professor of Obstetrics, University of Manchester); Ald. T. Halstead; Sir Thomas Tomlinson; Major E. F. Pilkington; Ald. J. Eastham; Mr. G. Gibson, C.H.; Miss L. G. Duff-Grant (Matron, Royal Infirmary, Manchester); Mr. N. G. Frank; Mr. C. N. Skinner; Prof. H. S. Raper (Professor of Chemical Physiology, Dean, University of Manchester); Dr. J. D. Ailverston; Dr. S. Hodgson, J.P.; Mr. W. Onions; Mrs. E. A. Watson; Ald. G. D. Hastwell; Mr. F. W. Boggis; Mr. J. Fielding; Prof. G. Jefferson, C.B.E., F.R.S. (Professor of Neurological Surgery, University of Manchester); Mr. R. L. Newell, F.R.C.S.; Prof. H. Platt (Professor of Orthopaedic Surgery, University of Manchester); Mr. F. Bussy; Mr. A. Cook; Ald. J. Shorrocks; Mr. W. A. Davies, C.B.E.; Mr. J. Sillavan; Mrs. F. A. Ogden; Mr. E. Hall.

Liverpool Regional Hospital Area.—Mr. J. F. Mountford; Prof. H. H. Stones (Professor of Dental Surgery, University of Liverpool); Mr. D. R. Owen, F.R.C.S.Ed.; Dr. T. H. Harker; Mr. E. Smethurst; Mr. A. Parkin; Ald. D. Plinston; Miss D. C. Keeling, O.B.E.; Miss M. Jones, O.B.E.; Prof. H. Cohen (Professor of Medicine, University of Liverpool); Dr. J. E. Nicole, O.B.E.; Miss A. L. Bulley; Mr. H. D. Ellidge; Mr. W. S. Rhodes; Mr. T. W. Harley, M.B.E., M.C.; Prof. A. L. Robinson (Emeritus Professor of Obstetrics and Gynaecology, University of Liverpool); Prof. T. B. Davie (Dean of Medical School, University of Liverpool); Prof. W. M. Frazer, O.B.E. (Professor of Public Health, University of Liverpool); Mr. F. Bidston; Ald. N. Birch; Miss A. D. Eills, M.B.E.; Mr. J. Taylor; Mr. E. E. Ashton.

MEDICAL ORGANIZATION IN DENMARK GENERAL PRACTICE

BY

K. H. BACKER

Medical Adviser to Department of Health

The development of medicine in Denmark has involved the working power of general practitioners being employed to a great extent in organizing out-patient care. The specialization of medical science, in itself likely to counteract this development, has resulted in an organized collaboration between the specialists and the general practitioners, the position of the latter being maintained as the bed-rock of out-patient care. The fact that the sickness benefit clubs, as supporters of the social sickness insurance, could already bring their influence to bear towards the end of the last century has been a determining factor of this development.

In 1892, with State approval, the sickness benefit clubs were obliged to grant their members *free* medical care by general practitioners, whereas medical care given by specialists was a voluntary benefit. The obligation to grant free medical care debarred the sickness benefit clubs from confining themselves to covering the expenses of the members in part according to the refundment scheme. This obligation forced them to enter into contracts with the doctors, and these contracts were made with the general practitioners. As the number of sickness benefit clubs increased—they now include three-quarters of the population—the position of the general practitioners became more important. One reason was that the number of specialists at the outset was so small that the out-patient care could base itself on their co-operation to a small extent only; besides, specialist care was more expensive than general-practitioner care.

The contract negotiations between sickness benefit clubs and doctors gave the latter a share in determining the organization of out-patient care. It was conducive to the general practitioners' keeping their central position, even after specialization within medical science had grown apace. To some extent, I suppose, it was due to the numerical superiority of the general practitioners—you could not do without them—but it was also due to systematic endeavours to organize the medical care service on the "family doctor" principle. This principle has been and is accepted unanimously by general practitioners and specialists as well as by the sickness benefit clubs.

The Family Doctor

According to the "family doctor" principle each family has its regular doctor, a general practitioner, to whom the members of the family always apply first for medical care. On his advice and reference a specialist may be consulted; when the specialist treatment has been finished, the patient is sent back to his family doctor with an account of examinations and treatment, if any. The same mode of procedure is adopted by hospitals and similar institutions in relation to the doctor admitting the patient to the hospital—normally the regular doctor of the family. This scheme has some advantages and some disadvantages. It limits specialist care to what is "necessary"; and it results in the family doctor's getting a thorough knowledge of his patients in the course of time, not only of their state of health but also of their social conditions, their milieu—knowledge of great medical importance which cannot easily be concentrated in one person if the service is not organized on the family doctor principle.

In contrast to the family doctor scheme is the medical care service, which does not attach importance to the establishment of a regular relationship between families and general practitioners, and which permits of free choice of doctor for each new case of illness and consultation with a specialist without reference to a general practitioner. Such a service does not make a point of limiting specialist care to what is "necessary"—i.e., to the difficult cases for which a non-specialist dare not be responsible. The result is that specialist care is given more frequently. This may at first sight appear an advantage. The fact that some cases will be treated by a specialist even when it is unnecessary may not change this view; nor

may the fact that some cases, although applying to a specialist, will not really be treated by one, for the same patient may have symptoms, and suffer from illnesses, coming under different specialties, and for practical reasons a corresponding number of specialists will not always be available to the patient.

The conclusive objection to such a service, however, is that the thorough knowledge of patient, family, and milieu, which in the family doctor scheme is concentrated in the regular doctor of the family, cannot be gathered by one person if the family doctor scheme is abandoned. Reports from hospitals and other health units, tuberculosis centres, medical laboratories, x-ray clinics, specialists, etc., which are now all collected in the family doctor's file, and which together with the family doctor's own observations constitute, when co-ordinated, immensely valuable material for judging the state of health of each patient, would be scattered to the four winds of heaven.

This is, in a nutshell, the supreme merit of the family doctor scheme, and it far exceeds anything that may be advanced in favour of its rival. At the same time I should like to point out that the family doctor scheme is the more rational, not only from a medical but also from an economic point of view. The education of the specialist is normally more prolonged than that of the general practitioner, and it is more difficult; in fact it cannot be obtained without a considerable contribution on the part of the doctor. So it is only reasonable that the services of the specialist should be more expensive than those of the general practitioner and that they should be employed only where "necessary."

Sickness Benefit Clubs

The sickness insurance of persons of small means is based upon voluntary membership of approved subsidized sickness benefit clubs. The total income of these clubs was in 1942 about Kr.107 million, about Kr.70 million of this being contributions and Kr.23.6 million State subsidies. The income limit for membership of sickness benefit clubs is at present Kr.6400 in Copenhagen, Kr.5700 in the provincial towns, and Kr.4700 in the country. The limit is based upon the taxable income. Children under the age of 15 years are insured in virtue of the contributions paid by their parents.

The benefits of the clubs are partly compulsory (provided by law): free medical care (not including specialist care, however), free hospital treatment, daily allowances according to special rules (up to Kr.6 a day against payment of a corresponding extra contribution), and free midwife and medical assistance on confinement. Other benefits are voluntary (to be fixed in the rules of the sickness benefit club): for instance, specialist care and medicine, dental care, nursing at home, etc. The voluntary benefits are often granted to a too small extent or not at all.

The payment of the sickness benefit clubs for general-practitioner care is made according to an agreement between the organizations of the clubs and the doctors. In all towns a fixed amount is paid per year per member, at present Kr.9.30 per member over the age of 15, nothing for children under that age. Married couples are considered as two members. The rates are now to be increased by about 50%. In the country the doctors are paid for services rendered—for instance, per consultation Kr.3.35, journeys up to 2 km. Kr.6, plus Kr.0.70 for each additional kilometre begun. Conveyance allowance is granted in the rural districts. Additional rates are allowed for special examinations and various surgical operations. The cost of medical care per member per year is somewhat higher in the sickness benefit clubs paying for services rendered than in those paying a fixed amount per year, at present on an average Kr.13 to Kr.14.

Patients have free choice of doctor. In Copenhagen the number of doctors participating in the sickness benefit club service is by contract limited to one doctor for 1,500 members. However, the proportion at present is 1 to 1,700. Outside Copenhagen the doctors' right to participate in the service is not limited; in the country, however, it is subject to the provision that the members must choose their doctor within a distance of 10 km. if practicable. The average number of members per doctor is somewhat lower in the country than in Copenhagen (about 1 to 1,200 to 1,300).

Practices may be bought and sold everywhere except in Copenhagen. The price of a practice amounts to approximately the gross income of one year.

Two Types of Club

We distinguish between class I sickness benefit clubs, which pay the doctors a fixed amount per year per member, and class II sickness benefit clubs, which pay for services rendered. In all class I clubs and in some class II clubs the members have to choose their doctor for a calendar year at a time, according to the agreement between sickness benefit clubs and doctors. A married couple must have the same doctor, and he then becomes the doctor for all the children too. It is the family doctor principle with the regular doctor-patient relationship that is operative here. It may be added that the relationship is not so regular that it cannot be broken in case of disagreement between doctor and patient. In some class II clubs, however, the members are entitled to change their doctor during the year. Few people avail themselves of this right, partly because these clubs are situated in country areas where the possibility of changing to a new doctor is small.

The method of payment of class I is that generally used in club practice, and in recent years it has had an ever-increasing extension at the expense of that of class II. It implies, too, the regular relationship between the insured persons and their doctor. It cannot be denied that the fixed annual amount is more closely related to the "family doctor fee" formerly much used in private practice. Nor can it be denied that the family doctor is more independent in his work when he is under no obligation to account for the number and nature of his services.

"Compulsory Reference" by General Practitioners

It is one of the most important assumptions of the family doctor scheme that specialist care can only be given through the sickness benefit club when the patient is referred by the general practitioner. This "compulsory reference" has been framed by sickness benefit clubs, general practitioners, and specialists in agreement. I am convinced that the sickness benefit clubs have realized the many advantages of the family doctor scheme, but it would not be unreasonable if economic factors had made themselves strongly felt. Specialist care is more expensive than general-practitioner care, and the clubs have wanted to grant only "necessary" specialist care, and have left the decision to the general practitioners.

This agreement between the three negotiating parties—sickness benefit clubs, specialists, and general practitioners—has in Denmark afforded a very firm basis for the family doctor scheme. In this connexion it has been a great help that the Danish sickness insurance from the start was planned as a family insurance automatically including children under the age of 15 years, and it has always been independent of whether or not the beneficiary was a wage-earner in a special employment. Insurance services in other countries did not permit of voluntary insurance of children and members of the family who were not wage-earners until much later. The balance of the Danish family doctor scheme has made it more viable. It has among other things involved the organization by central and local bodies of preventive tasks based on the family doctor scheme, in the first place assigning diphtheria vaccination to the general practitioners, later on general health care of expectant mothers, and now general health care of children from 0 to 7 years. In most other places these tasks are assigned to doctors and institutions specially appointed and set up for the purpose.

Regulations Governing Specialists

Besides the agreements between sickness benefit clubs and doctors the family doctor scheme has been consolidated by certain provisions in the collegiate rules of the Medical Association. Thus a doctor having a certificate of competence for a specialty and wanting to furnish specialist service is not allowed to render general-practitioner care. We have been aiming at a clear definition of general practitioners and specialists because we wanted organized collaboration on the family doctor principle. The provision does not apply to private patients, but they are treated less consistently on this principle than the club patients and must consequently put up with the draw-

backs of not having a regular doctor. In the Medical Association's rules is a provision to the effect that a specialist, when a patient is referred to him in writing, shall directly inform the referring doctor of the result of examination and treatment; he must not refer the patient to other doctors without the consent of the referring doctor; and he must leave the further treatment of the patient to the referring doctor as soon as the specialist treatment is finished.

It is hardly an exaggeration to say that the family doctor scheme has been carried through more consistently in Denmark than in most other places. This is partly due to the fact that the sickness benefit clubs have adopted this scheme and have given it a dominating position by their growth. It is also due to the fact that Denmark is well provided with general practitioners who have received a good and uniform education. The specialization of medical science has of course led to an adaptation of the family doctor scheme to the requirements of the age. Here we have been faced with the same problems which Great Britain is now trying to solve through reorganization.

Problems of a Health Service

1. *General practitioners must have sufficient time for their work and for continued studies.* It must be admitted that it has been somewhat difficult to attract the attention of the sickness benefit clubs to this requirement. The principal method of payment is, as mentioned, a fixed amount per year per member. This amount has hitherto been very small; with the present price level it is Kr.9.30 per member per year, any person over the age of 15 being regarded as one member, and children under 15 being covered by the breadwinner without additional fee. This has resulted in an expansion of practices to a higher level than desirable. The work itself has made greater demands—of quality as well as quantity—and the patients as well as the doctors have every reason to regret that generally the doctors have not the necessary time for their work.

However, some understanding of this state of affairs on the part of the sickness benefit clubs is now perceptible; recently it has been possible to carry on discussions on the basis that a practice of average size—i.e., about 1,500 patients—should yield a reasonable net income, which it has not done so far. At the same time the parties have agreed about appropriate measures to prevent excessive enlargement of practices. That means one step nearer the aim of sufficient time; and it will be possible to continue this development so far as the number of available doctors allows.

2. *Up-to-date laboratory services should be available to the general practitioners.* We are on the point of having solved this question in a way satisfactory to the doctors as well as to the population. As early as 1922 the general practitioners in Copenhagen established their own central laboratory, which since then has developed into a large institution rendering the general practitioners all the technical assistance they need for examinations. Doctors may send material for examination, or they may send their patients to the laboratory for investigation of metabolism, for electrocardiography, test meals, etc., and for production of material for examination (blood tests and the like), where this is best done at the laboratory.

The laboratory is operating to the complete satisfaction of everyone. At the outset we had a central laboratory with branches, but we found that the distances in Copenhagen (scarcely 1 million inhabitants) made it unnecessary, for the central laboratory in fact was situated in the centre. Outside the capital the numerous public hospitals are operating as laboratories for the doctors in a similar way.

The technical assistance rendered to the general practitioners by the laboratory seems in England to be one of the arguments for group practice. In Denmark we did not feel tempted to change over to this form of practice because we know from experience that a really efficient laboratory cannot nearly be utilized to its capacity by the ten doctors supposed to constitute a group; and a laboratory which is not quite efficient can hardly be adequate.

3. *X-ray services should be available to the general practitioners.* In Copenhagen the sickness benefit clubs pay for x-ray examinations on patients referred by general practitioners to the many private x-ray clinics, most of which are fully efficient. Outside the capital x-ray examinations are under-

taken at the public hospitals, which are situated within easy distance even of the country population. It seems as if in England this question is to be solved by health centres equipped with x-ray services, but in view of the above it will be understood that we have been under no temptation to try this solution. Here the same thing may be said to apply: ten doctors cannot nearly utilize a really efficient x-ray clinic to its capacity; and a clinic that is not fully efficient does not solve the problem.

4. *Clinical assistance by specialists, for examination as well as treatment, should be available to the general practitioners.* In this field the Danish National Health Service is still insufficient. This is due partly to the fact that we have not got the desirable number of specialists all over the country, partly to the fact that the sickness benefit clubs have been too reluctant to pay for the necessary specialist care, having to grant only free general-practitioner care under the Act. The sickness benefit clubs have shifted the expense of specialist care on to the public hospital service, apart from specialist care for eye diseases and diseases of ear, nose, and throat. For these specialties there is an ample number of specialists all over the country; and the sickness benefit clubs have an agreement with them according to which the members receive free specialist care when referred for such treatment by their family doctor.

So far as I can see, another argument for group practice is that it is easier to collaborate with specialists attached to the group. If the non-specialists of the group are to make a contribution themselves, however, ten doctors will not be able to utilize the specialists to their capacity. Ten doctors may utilize an eye specialist and an ear, nose, and throat specialist provided that they refer every case of illness within these specialties. As regards the other specialties it will not be possible according to Danish experience. All the talk about group practice in England has not failed to stir some minds in the small country over the North Sea; but outside the few who are always excited about anything that is brand new the idea has not met with enthusiasm.

Specialist Diagnosis for Out-patients

As regards the other specialties the doctors often have to send their patients to hospitals in order to have them examined and treated by specialists. Since in many cases this is done merely because the doctor, in spite of laboratory and x-ray facilities, cannot solve a diagnostic problem, the hospital service has considered allowing the hospital specialists to make the diagnosis and advise out-patient care so as to avoid the expense of hospital admissions. Only in the capital may the general practitioners to some extent be in consultative collaboration with the practising specialists.

The medical profession would prefer a further development and extension of this scheme, for we have some hesitation in contributing to the increase of out-patient departments by attaching specialist care to the hospitals. Even if the specialist care supposed to be afforded by hospitals in the form of out-patient service is meant merely to help doctors to make the diagnosis (after which the treatment is referred to the general practitioners), diagnosis often involves therapy; and then you are well on the way to the out-patient clinic or health centre. This development is hastened by the fact that some forms of treatment require hospital equipment and other auxiliary services, and are therefore already undertaken at the hospitals in the form of out-patient care. Apart from specialist care requiring the auxiliary services of the hospital, we want this care to be given by practising specialists, because in that way one can be sure that the patient is in fact treated by a specialist. The large out-patient departments will always have a considerable staff of young doctors completing their training. They very often have to work rather independently without the clinic's specially trained doctors' being able to supervise the work of each person. So it is somewhat problematic—as circumstances are in Denmark at least—to talk about specialist care in connexion with out-patient care. For that reason and because we are of opinion that the work of the specialist as well as that of the general practitioner in most cases is done best in private, we have so far as possible tried to avoid a development of actual out-patient departments—and with success in so far as there are out-patient departments in the capital only. They

are few, however, and in the form of closed departments which do not receive patients who have not been referred by their doctor. As the sickness benefit clubs in the capital are now more than willing to grant specialist care by practising specialists, it seems possible to have all specialist care (apart from that requiring hospital treatment) assigned to the practising specialists. It is to be hoped that a corresponding development will prove possible outside the capital.

Having a developed family doctor scheme—an organized collaboration between the general practitioners and the medical laboratories, the x-ray clinics, the practising specialists, and the hospitals. We consider this arrangement sound. Even if the system is far from being perfect in various points, we are under no temptation to change it. Nor do we feel any great pressure from the public or the politicians, though I dare say we are prepared for it. It is a consequence, I suppose, of our not being so anxious to "socialize" the doctors, which may be explained by the fact that Danish doctors have been subject to a gentle process of socialization over several years by their relation to the sickness benefit clubs. The final result has been that "few have too much and fewer too little."

Under these circumstances it has even been possible to plan a pension scheme for the Danish medical profession, a scheme which is now ready for implementation. It rests upon provisions in the agreements between the public hospital service and the hospital doctors and between the sickness benefit clubs and the doctors participating in the service, according to which pension contributions are paid by the hospital service and the sickness benefit clubs into the "Pension Fund of the Medical Association," which together with a financial body administers the subscriptions and the payment of old age and invalidity pensions. Being incorporated in these agreements, the scheme is compulsory for all the doctors covered by them—i.e., the great majority of Danish doctors.

It is evident that the problems involved in the organization of medical care differ in Britain and Denmark, but even so this account may be of interest to doctors in England. The ends aimed at in Britain—time for the doctors, technical assistance, clinical assistance by specialists, in brief, an effective medical scheme—may also be gained through the channels followed in Denmark without changing the form of practice from individual to group practice and without making a civil servant of the doctor, provided that a sufficient number of doctors is available. It does not matter then whether the sickness benefit club or the State is the doctor's employer.

RADIO-ACTIVE SUBSTANCES BILL

This Bill was recently discussed in the House of Lords (May 24, p. 747). Clause 5 prevents the use for therapeutic purposes of apparatus which produces radiation except under licence of the Minister of Health. The British Medical Association is advised that this would cover radio-active substances, deep x-ray therapy, short-wave therapy, ultra-violet and even radiant heat lamps. This restriction does not relate to the use of such apparatus for medical, surgical, or dental diagnosis, but it strikes a blow at the principle that once on the Register a practitioner should not be prevented by law from treating patients by any method without restriction.

In 1945 the Association appointed a special committee to consider this problem. That committee recommended to the Ministry that the use of radio-active substances should be restricted for an experimental period of, say, two years, after which these substances should be available, as other therapeutic substances are, to all registered medical practitioners. In brief, the restriction should operate only during an experimental period to enable adequate knowledge to be gained of the dangers and necessary protective measures. Representations are being made to this effect.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. M. P. Leahy, at 39, Harley Street, W.1 (Langham 4012); Mr. Harold Park, F.R.C.S., at 40, Wilbury Road, Hove, 3, Sussex; Dr. James S. Young, M.R.C.O.G., at 37, Harley Street, W.1 (Langham 3556).

HEARD AT HEADQUARTERS

Anonymity on the Air

About thirteen years ago the General Medical Council expressed the view that registered medical practitioners "should broadcast anonymously." The phrasing is a little ambiguous, but the meaning was that if registered medical practitioners felt compelled to take to the air they should not have their names announced. The appearance of television has reopened the question. May a medical practitioner allow his lineaments to be revealed on the television screen? Suppose by some extraordinary development that all broadcasting were accompanied by television, is a medical practitioner on facing the microphone plus the television camera to wear a mask or to have a coat dropped over his head like a criminal under public arrest? People naturally like to know who is talking to them, and the same applies in broadcasting. The Central Ethical Committee of the Association some time ago discussed this question and presented to the General Medical Council a considered case for permitting practitioners, when giving broadcast talks on medical subjects, to appear in television and to be announced by name. But two committees of the General Medical Council have now shaken their heads over the proposition and see no reason to modify the opinion expressed in 1934. Advertising by any professional man, of course, is to be deplored, but apparently other professions do not carry the embargo to this extent. It does seem a little anomalous when a Brains Trust or other debating team is on the wireless to have men in other professions duly announced while the medical representative, if there is one, is referred to mysteriously as a well-known physician (or surgeon, or psychiatrist, as the case may be). At one and the same time it gives the anonymous individual an undue importance and casts a slight slur upon him.

The Scottish House

It is interesting to learn that the Scottish Committee is considering an appropriate commemoration of the officers and officials, past and present, of the Association in Scotland in the Scottish House in Edinburgh. Scotland has produced some great leaders, several distinguished Presidents, and a number of men who have made their mark at Headquarters in London, including the present Chairman of the Representative Body. Dr. Craig's long and able Scottish secretaryship, which has lately ended, should have some outward and visible reminder in the place where he worked. The Scottish House of the Association was opened at almost the same time as the Tavistock Square premises in London. No. 6, Drumsheugh Gardens was first taken, and then, two years later, No. 7, and the two houses were turned into one at the first floor so as to provide an excellent conference room for 300 people. It is in this room that it would be interesting to have panels with the names of those who have served the Association in various official capacities north of the Tweed.

The G.M.C. Bill

The draft Medical Bill for a procedure reformed in many respects has passed through its final stage of approbation by the General Medical Council. There have been conferences between the B.M.A. committee and the Defence Societies on the one hand and the Legislation Committee of the G.M.C. on the other. Some of the points which the outsiders suggested have been accepted, and others have not been pressed because of the desirability of getting an agreed Bill if possible. Any considerable divergence of view would have spoiled the Bill's chances of success. The points incorporated in the Bill are mostly small but useful ones, as, for example, the requirement that if an appeal is lodged by a practitioner against the direction to erase his name the direction shall be suspended until the appeal is determined. Justice has, in the main, at least of late years, always been done by the G.M.C., but the new measure will help to ensure not only that justice is done but that justice appears to have been done.

Correspondence

Evidence for Spens Committee

SIR,—I am given to understand that the B.M.A. has lent its services in the form of the use of its address, and part of its secretariat, to further a wholly pernicious inquiry for the latest Spens "Gestapo committee." I must protest strongly against the terms of the document issued by this Evidence Committee. It would appear that the B.M.A., is rapidly descending the slippery slope towards becoming a collecting house for evidence for the enslavement of the profession.

Why should it be necessary to set a "ceiling" to the earnings of any person in a free service? Does not the profession realize that all the codification, classification, and Nazification in this and other documents can only lead to enslavement of the profession and populace? When are we as an Association going to realize the gravity of the situation whose coming we are assisting by these questionnaires, etc.? It is to be hoped that consultants will have nothing to do with this, and they will not be led by the usual timid *vis a tergo* of our so-called leaders.

There are still many doctors sufficiently alive to the dangers of National Socialism to deprecate the all too apparent eagerness of the Association to co-operate with the Government in the establishment of a bridge-head of the full-time salaried State service. The circular letter to consultants certainly did not make it clear that this information was sought solely for the benefit of whole-time servants of the State. It is high time that the mechanism of the Association was brought to bear wholeheartedly on protecting the independence of independent practitioners, by whom, and presumably for whom, the Association was founded.

Let us have a bold lead and less of the Duke of Plaza Toro and a little more resistance to encroachment on liberty.—I am, etc.,

London, W.1.

DAVID HALER.

** The Secretary of the B.M.A. comments: The new Spens Committee is concerned only with the range of remuneration of consultants and specialists engaged in a public service on a full-time basis, and not undertaking private practice. The Committee has been instructed to pay due regard to the financial expectations of consultants and specialists in the past; it must therefore obtain reliable information. The previous Evidence Committee carried out a similar inquiry to the satisfaction of general practitioners. The word "ceiling" does not imply that a practitioner will be unable to earn more than that figure.

Regional Hospital Boards: Salaries

SIR,—We are informed (*Supplement*, June 7, p. 116) that the Minister of Health proposes to offer salaries of between £2,000 and £2,500 for the appointments of chief administrative medical officers of the fourteen hospital boards. It is to be hoped that the Association will oppose these salaries, even to the extent of black-listing the posts if necessary. These fourteen appointments will be among the very highest in the field of medical administration. In other professions a man who reaches the top of the tree does not rest content with £2,500. Are these fourteen men who will administer the nation's hospitals to be considered of less value to the community than are judges? A judge receives £5,000 a year. The Association recently drew up a suggested scale of salaries for medical officers of health and other full-time salaried officers. On this suggested scale the M.O.H. of a large county or city would earn £3,000. The whole scale would be thrown out of focus if the administrative medical officer of a regional hospital board received only £2,500.

Although clinicians and administrators sometimes make the mistake of disparaging each other, the general public is—not unwisely—more and more tending to equate the two, to think that the doctor who specializes in paediatrics or neurology is worth about the same as the doctor who specializes in hygiene or administration. Consequently, if these low salaries are offered to the leading specialists in administration, we can expect sooner or later that similar salaries will be offered to

outstanding clinicians. Are the chief administrative officers of the National Coal Board paid as little as £2,500 per annum? If not, why should the medical administrator receive less than the administrator in other fields?—I am, etc.,

A MEDICAL ADMINISTRATOR.

Association Notices

Nathaniel Bishop Harman Prize

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize in the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has previously been published in the medical Press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL,
Secretary.

Diary of Central Meetings

JULY

- 22. Tues. Council, 11 a.m.
Annual Representative Meeting, 2 p.m.
- 23. Wed. Annual Representative Meeting, 10 a.m.
Annual General Meeting, 12.30 p.m.
- 24. Thurs. Annual Representative Meeting, 10 a.m.

Branch and Division Meetings to be Held

EAST HERTS DIVISION.—Wednesday, July 9, 2.30 p.m. Visit to Messrs. Allen and Hanbury's factory at Ware.

LANCASHIRE AND CHESHIRE BRANCH.—At Chester Town Hall, Thursday, July 10, 2.30 p.m. Annual meeting. Election of Officers, etc.

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, W.C., Tuesday, July 8, 2.30 p.m. Eighty-ninth Annual General Meeting. Agenda: Report of Branch Council for the year 1946-7; report of Branch representatives on Central Council, 1946-7; report as to elections of officers for 1947-8; address by incoming President.

SHROPSHIRE AND MID-WALES BRANCH.—At Eye, Ear, and Throat Hospital, Shrewsbury, Tuesday, July 8, 3.15 p.m. Clinical meeting. Mr. S. W. G. Hargrove: "Hoarseness."

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.—At Herefordshire General Hospital, Hereford, Thursday, July 10, 2.30 p.m. Annual meeting.

TRADE UNION MEMBERSHIP

The following amendment is made to the list of "closed shop" authorities:

County Borough Councils: Add Barnsley.

Non-County Borough Councils: Delete Barking.

LONDON SATURDAY JULY 12 1947

CHOICE OF DRUGS IN THE TREATMENT OF DUODENAL ULCER*

BY

A. H. DOUTHWAITE, M.D., F.R.C.P.

Physician to Guy's Hospital

Much has been written during the last quarter of a century on dietetic control of duodenal ulceration, whereas the rational use of drugs has been to a great extent ignored. It is on the latter therapeutic measure that I present the following observations.

Belladonna

The use of belladonna in the treatment of duodenal ulcer has been practised widely for 25 years. Experiments on animals, and later on human beings, led to the belief that the drug caused a considerable reduction in acid output by virtue of a paralysing action on the vagal nerve-endings. Thus Bennett (1922) emphasized the value in this respect of washing the stomach with a dilute solution of atropine before meals. It soon became standard practice to give belladonna or atropine, usually 5 minims (0.3 ml.) of tincture of belladonna before alternate two-hourly feeds (Ryle, 1923) and 1/100 gr. (0.65 mg.) of atropine sulphate hypodermically at night. Ryle stated that belladonna given in this way would cause dry mouth, relaxation of the pylorus and thus reflux of duodenal contents, and modification of the gastric acidity more than that produced by alkali. Schick (1910) declared that its chief value lay in overcoming pylorospasm, and Crohn (1918) refers to the transient and poor effects of atropine on gastric acidity.

No serious criticism of the use of belladonna as an acid depressant arose until in 1938 Davidson and Nicol communicated to a meeting of the Gastro-Enterological Club the results of experiments which showed that even toxic doses of atropine had no constant or marked influence on gastric acidity. Later Nicol (1939) published a paper reiterating that atropine failed to influence gastric secretion and that its value lay in its antispasmodic action.

If belladonna has in fact any action in reducing gastric secretion it can only be by virtue of its paralysing the vagal terminations. It follows, therefore, that only reflex secretion would be abolished, whereas the more important and lasting humoral secretion would be untouched. On theoretical grounds one would expect some diminution in acid output to be produced by belladonna, the degree of change being influenced by the character of the food—appetizing or monotonous—the personality of the subject, and the period of time following ingestion of food. It would be inconceivable that a therapeutically effective reduction of acidity could be produced by belladonna in any dosage.

In order to confirm Nicol's work I investigated the effect of *l*-hyoscyamine on the test-meal curves of 25 patients with hyperchlorhydria and duodenal ulcer. It will be

remembered that the action of belladonna is largely due to atropine, and that atropine is racemic hyoscyamine. Furthermore, the peripheral effect of atropine is almost entirely due to its *l*-hyoscyamine component. As it is this action which concerns us, and as the central stimulant effect of both *d*- and *l*-hyoscyamine is unwanted, the latter drug was clearly one of choice. Hyoscyamine sulphate, 1/80 gr. (0.8 mg.), was given by mouth night and morning for three days. On the fourth day, an hour after the morning dose had been taken, the test-meal was given. It will be appreciated that this is high dosage, equivalent in alkaloid value to 36 min. (2.1 ml.) of tr. belladonnae per dose. Within 36 hours it produced persistent dryness of the mouth, thirst, and dilatation of the pupils. Duodenal ulcer pain, if previously present, disappeared as soon as these signs were manifest, yet it will be seen from Figs. 1a, 1b, 2a, and 2b that the effect on acidity was so slight that it is highly improbable that it would have influenced the pain. Although in a few instances the depression of acidity was more than that shown in these graphs, in no case was it great or prolonged.

If, then, it be agreed that the effect of belladonna on gastric acidity can be disregarded, why is it that it does

Fig. 1a.—Case of duodenal ulcer. Curve of free HCl during gruel test-meal.

Fig. 1b.—Curve from same patient as Fig. 1a taking hyoscyamine.

Fig. 2a.—Further case of duodenal ulcer. Gruel test-meal.

Fig. 2b.—The same as Fig. 2a during hyoscyamine treatment.

* Based on a communication to the Brighton and Sussex Medico-Chirurgical Society on April 3.

in fact relieve pain? Of such action there can be no question provided that adequate quantities be given. No benefit is derived from belladonna unless persistent dryness of the mouth is produced by it. The customary dosage is therefore useless. In practice it will be found that 30 min. (1.8 ml.) of the tincture of belladonna, 1/100 gr. (0.65 mg.) of atropine sulphate, or 22 min. (1.3 ml.) of liquid extract of hyoscyamus given four-hourly will be effective. Yet more efficacious is 1/120 gr. (0.54 mg.) of *l*-hyoscyamine twice daily (Douthwaite, 1939).

It is well known that the belladonna alkaloids have a pronounced effect on the motility of the gastro-intestinal tract, especially in the direction of quelling abnormal contractions. It is also usual to note excessive gastric peristalsis, often combined with pyloric spasm, in patients suffering from duodenal ulcer. Furthermore, rapid emptying of the stomach is common not only during the active phase but also during periods when healing of the ulcer seems to be established. Numerous observers have noted how this hypermotility is abolished by full doses of atropine. It can be demonstrated radiographically, and was noted by Wolf and Wolff (1943) in their experiments on a patient (Tom) with a gastric fistula. They showed, furthermore, that atropine resulted in a great prolongation of emptying time.

If it can be accepted that the pain of duodenal ulcer is due to abnormal contractions of muscle fibres in the stomach or duodenum, or both, the benefit conferred by belladonna can be understood. There are two schools of thought in regard to the pain-producing factor: the one favouring muscular contractions and increased tonus, resting on the observations of Bolton (1928), Christensen (1931), Hurst (1911), Ryle (1926), and Poulton (1928); the other stressing the importance of acidity, based on the work of Palmer (1926), and recently of Bonney and Pickering (1946). The evidence derived from careful clinical experiments by the latter school certainly presents convincing grounds for the belief that a certain level of acidity, varying from case to case, will, if reached, be directly responsible for ulcer pain.

It does not, however, exclude the possibility that the muscular contractions may also cause pain or, in fact, may be the usual excitant of pain production. An argument often put forward is that if an intragastric balloon fails to record a rise of tension coincident with pain, increased muscular tonus cannot be incriminated. Such a conclusion is not justified. Only if an increase of gastric tonus as a whole should occur would one expect it to be registrable manometrically. Localized spasm could not possibly influence the tension within the balloon, yet it might well give rise to pain.

The "acid hypothesis" fails to explain certain common features of pain in uncomplicated duodenal ulcer—namely: (1) Its occurrence at 2–3 a.m. and its spontaneous subsidence even if no food or alkali is taken. The chart of gastric acidity (Fig. 3) taken during sleep shows it to be lower at 2 a.m., which was the hour when pain usually awakened this patient.

(2) Its spontaneous subsidence before meals if the meal is postponed. (3) Its lessening or disappearance within half an hour of lying down. (4) Its relief from the application of heat to the abdomen. This is known to inhibit gastric

and intestinal peristalsis (Bisgard *et al.*, 1942). (5) Its rapid relief by CO₂—producing antacids, whose effect on acidity is transient as compared with the non-gas-producing antacids such as trisilicate. (6) The invariable relief afforded by full doses of belladonna alkaloids.

It is reasonable also to assume that the pain of gastric and duodenal ulcer has the same mechanism of production; yet in the former case gastric acidity is usually within normal limits and there may, in fact, be no free hydrochloric acid throughout digestion.

FIG. 4.—Chronic duodenal ulcer. Note hypertonicity and pronounced peristalsis after four weeks' milk-drip.

FIG. 5.—The same as Fig. 4, one day later, an hour after hyoscyamine sulphate, gr. 1/80 (0.3 mg.).

FIG. 3.—Duodenal ulcer. Free HCl curve during night. Samples removed hourly.

postponed. (3) Its lessening or disappearance within half an hour of lying down. (4) Its relief from the application of heat to the abdomen. This is known to inhibit gastric

Finally, a positive argument in favour of the muscular tension theory is afforded by radiographic observations. The radiographs (Figs. 4 and 5) of the stomach of a sufferer from duodenal ulcer were obtained within 24 hours of each other. Continuous pain was being experienced while

aking Fig. 4, in which a series of peristaltic waves are seen. In Fig. 5 gastric tone and motility are strikingly lessened as the result of 1/80 gr. (0.8 mg.) of hyoscyamine sulphate. The patient was entirely free from pain. Numerous observations have shown the same sequence of events. It follows from this that the operation of vagotomy or duodenal ulcer is wholly unjustifiable. Belladonna can achieve all the good results claimed for such surgery without the danger and permanent mutilation it entails. It is probable that two factors produce pain in peptic ulcer—abnormal muscular contractions, and a chemical stimulus provided by hydrochloric acid. The justification for the use of belladonna is thus established. We have now to consider the control of acidity.

Antacids

No matter what views are held on the mechanism of peptic ulcer pain production, it is common ground that free hydrochloric acid is of great importance in preventing the healing of the ulcer. It is reasonable, therefore, to seek to neutralize this acid so long as an ulcer is present. Once healing has been secured the need is far less, if indeed it exists at all. It should be noted here that Ryle and Bennett (1937), from a follow-up of 100 students subjected to test-meal analysis in 1921, concluded that there was no association between degrees of gastric acidity and the development of dyspeptic troubles.

In point of fact all the drugs commonly used to neutralize gastric hydrochloric acid have such a transient action as to be valueless. The fleeting action of sodium bicarbonate, calcium and magnesium carbonate, and tribasic phosphates is too well known to require further emphasis. Experiments carried out by E. B. French and myself on patients with peptic ulcer (Douthwaite, 1939) showed, furthermore, that aluminium hydroxide gel and magnesium trisilicate when given hourly failed to neutralize hydrochloric acid for more than a quarter of an hour. The former when given by continuous drip, 1 oz. (28 ml.) hourly, was likewise ineffective. Figs. 6a, 6b, and 6c illustrate the short action of these substances. It is true

One of the reasons for the transience of antacid action in cases of duodenal ulcer is that the stomach empties so quickly. The same conclusion was reached by Nicol (1939) in respect of the fact that hourly feeds of milk fail to produce neutralization. He also showed that neither hourly nor two-hourly feeds of milk foods, vegetable purée, eggs, and fish, in conjunction with carbonates, would cause lasting depression of gastric acidity; in fact, two-hourly feeds containing more protein are more effective than hourly milk meals.

The only satisfactory way to neutralize gastric hydrochloric acid for days on end is to give milk by drip-feed through a Ryle's tube passed into the stomach. Five pints (2.84 l.) in 24 hours may be completely effective, as is shown in Figs. 7a, 7b, and 7c. The patient is seldom intolerant of this treatment, especially if the tube be passed through the nose. It is withdrawn and cleaned twice a week, and the drip can be discontinued at the end of three to four weeks. When such treatment is impracticable the next-best measure is to give 1/2 oz. (14 ml.) of olive oil (this delays emptying and reduces acid output) and 1/2 oz. (15.5 g.) of magnesium trisilicate in 8 oz. (227 ml.) of milk two-hourly, between two-hourly main feeds. These should consist of porridge, egg, milky foods, bread-and-butter, fruit juices, purée of fruit and vegetable, fish, and chicken. In fact, if chemical irritants—for example, mustard, spices, vinegar, and alcohol—are avoided and if other food is free from gross roughage, all the common foods may be safely taken from the beginning of treatment. If a milk-drip is used, then three meals a day may be given in addition to the milk.

FIG. 7a.—Duodenal ulcer. Gruel test-meal (1/4-hour samples).

FIG. 7b.—Same case as 7a. Continuous milk-drip, 5 pints (2.84 l.) in 24 hours for eight days; thereafter in daytime only. First rise of acidity due to interruption of drip. The later rises coincided with nights when the drip was suspended.

FIG. 7c.—Shows the feeble antacid effect of 5 oz. (142 ml.) of milk given hourly.

FIG. 6a.

FIG. 6b.

FIG. 6c.

FIGS. 6a, 6b, and 6c.—Free HCl curve showing the transient effect of aluminium hydroxide and magnesium trisilicate.

but in a long series one meets with instances in which one or other of the antacids appears to have a prolonged action, but it is the effect on the majority which is of importance.

Anxiety

After considering hypermotility and hyperacidity, our third and last problem is the control of anxiety, the effects of which are inimical to healing. This has already been done in part by blocking vagal impulses with hyoscyamine. The choice of a suitable cerebral sedative is not a matter of great difficulty. Phenobarbitone answers the purpose in the majority of cases. It may, however, prove unsuitable by causing skin rashes, fever, giddiness, and incoordination. More commonly it produces intense depression of spirits and disinclination to co-operate in the full treatment of peptic ulcer. Yet again, it may

completely fail to relieve anxiety and restlessness unless given in excessive doses. If 1 gr. (65 mg.) thrice daily fails to produce the desired effect it is wiser to change the drug than to increase the dosage. It should be borne in mind that phenobarbitone is an indifferent hypnotic, and that at night it is usually necessary to give a more potent soporific—for example, "sodium amytal," 3 gr. (0.2 g.).

When phenobarbitone fails a state of mental and muscular relaxation can be achieved by the use of cannabis indica. This drug has fallen into undeserved disrepute because of the danger of addiction, and even more because its preparations are often inert. The former risk is very slight when cannabis is used therapeutically for a limited period. It is certainly far less than that entailed by the use of opium and its derivatives. Taken by a patient resting in bed, and thus removed from any suggestion of conviviality, it produces a languorous state and sense of well-being, without the flights of imagination for which it is taken by the addict. Furthermore, it does not cause constipation, and the appetite is unimpaired. In fact, it may lend enchantment to the dietary.

Extractum cannabis (*B.P.C.*) is the preparation of choice; the tincture has a most unpleasant taste, and its resin is precipitated by the addition of water. The recommended dose of 1 gr. (65 mg.) is too small to be effective. Four times this amount should be given in capsules four times daily. The frequency of administration is adjusted to the result. It will allow of continuous drip-feeding in patients who would otherwise be intolerant of it. It is seldom necessary to give the drug for longer than two weeks, and a supply should never be left in the patient's charge. I have used the physiologically tested extract and have found it to be active, but it is as well to procure only a small stock at a time and to keep it at a low temperature—10° C. The effectiveness of the drug in inducing, presumably by central action, relaxation of the stomach is well illustrated by Figs. 8a and 8b. Symptomatically this patient suffered

Fig. 8b.—Same case as 8a when taking 4 gr. (114 ml.) of ext. cannabis four times daily. Stomach relaxed; stenosis revealed.

Harmful Drugs

In conclusion a brief reference to chemical substances which may aggravate symptoms of ulcer should be made.

Tobacco.—Experimental evidence favours harmlessness of smoking to patients with chronic ulcer. Neither rate of emptying of the stomach nor acidity can be shown to be appreciably affected. As against this it is a spontaneous observation of countless sufferers from duodenal ulcer that the pain, in the active phase of the disease, will always be produced or, present, aggravated by the smoking of a single cigarette. Again on inquiring into change of habits preceding a relapse, how often does one find that the only prophylactic measure which has lapsed has been abstinence from tobacco. It may well be that direct irritation of the gastric and duodenal mucosa is set up by pyridine, furfural, and acrolein, which are present in tobacco smoke and which are swallowed in saliva. I have no doubt that smoking should be limited—a pipe after breakfast and another after dinner—throughout the life of the patient.

Mustard, vinegar, curry, and strong alcoholic drinks and the like are chemical irritants and should clearly be avoided. For the same reason chloral hydrate is an unsuitable hypnotic for the sufferer from peptic ulcer.

Aspirin.—The possibility that aspirin might act as an irritant to the gastric mucosa, and thus cause melaena, was raised by me some years ago (Douthwaite, 1938). Later, Lintott and (Douthwaite and Lintott, 1938) carried out gastroscopic observations to determine whether this was in fact the case. We were able to show that an inflammatory reaction developed around particles of aspirin lying on the lesser curvature in 80% of subjects. The greater-curvature mucosa failed to show this change, no doubt because it is more protected by mucus. The failure of Wolf and Wolff to produce an aspirin reaction in the mucosa of Tom may be attributed to this fact or to their subject's belonging to the 20% resistant group. Since our communication on this matter confirmatory evidence has been plentiful. We were able to show that calcium aspirin in solution was entirely free from harmful effects. When the drug is indicated it is this form which should be prescribed.

After-treatment

Drugs have but little place in therapy once the ulcer has healed. That is to say, after two months of thorough treatment it is seldom necessary to add drugs to the advice we give for the regulation of the patient's habits. Adequate time for meals, thorough mastication, extra food between meals, avoidance of chemical irritants, nine hours in bed nightly, and the refusal to attend to the telephone during

Fig. 8a.—Chronic duodenal ulcer with clinical signs of stenosis. This is masked in the radiograph because of powerful peristalsis.

from pyloric obstruction, yet the emptying rate, determined radiologically, was rapid. The second radiograph (Fig. 8b), taken after treatment with cannabis at the same time, after a barium meal, shows that the rapid emptying was the result of hyperperistalsis and that true obstruction was present. This was confirmed at operation.

meals or at night are far more important than dietary schemes, which are unnecessary, and drugs.

We know that the high gastric acidity persists and that the exaggerated peristalsis often subsides if the patient is free from worry and stress. The first sign that it is returning is usually that of vague discomfort before food or of waking in the night for no apparent reason. I believe that this gastric unrest precedes duodenal ulceration. If I am right its prompt control should prevent the relapses which hitherto have been a reproach to our therapeutics. Therefore, when such early symptoms are noticed, or again during periods of mental fatigue, worry, and stress, the administration of belladonna alkaloids should be resumed and be continued until the patient has been symptomless for a week. It is especially the night dose which is of value. Alkaline or antacid preparations have no place in therapeutics at this stage: they mask symptoms and encourage relapse.

Summary and Conclusions

The value of belladonna and its correct administration in treatment of duodenal ulcer are described. The relationship of ulcer pain to acidity and hypermotility is discussed. The use of antacids is considered. The value of phenobarbitone and cannabis indica is described. Reference is made to certain substances in common use which aggravate peptic ulceration.

Belladonna reduces gastric and duodenal spasm and the emptying rate of the stomach. It does not affect acidity. To be effective the dose must be large enough to cause persistent dryness of the mouth. The operation of vagotomy is unjustifiable. Alkalis and other antacids have such a transient and variable effect on gastric acidity that they might well be discarded as of little value. If given they should be combined with the administration of olive oil. Their danger lies in the masking of symptoms while the disease progresses. Continuous milk-drip-feeding often completely neutralizes free hydrochloric acid in the stomach. Cannabis indica is a valuable sedative for use in the acute phase.

The cannabis indica used in these experiments was kindly supplied by British Drug Houses, Ltd.

Dr. Simon Flexner, who was born in 1863 and died in 1946, is commemorated in a pamphlet issued by the Rockefeller Institute for Medical Research, printing speeches delivered on June 12, 1946, at a memorial meeting. In 1902 the Board of Directors requested Dr. Flexner to state his views on the establishment of a research institute, and in 1903 he went to New York to take charge of the Rockefeller Institute's pathological laboratories, becoming Director of the Institute in the same year. One of the speakers quotes from a speech he made in 1933: "There are no closed compartments in nature into which man, animals, and plants can be separately placed. All are related organically and, as we may say, united physiologically and pathologically. . . . If, therefore, we would learn, and through learning grow more powerful and effective to prevent and cure disease, to lengthen life and to increase happiness through security in all its various forms, then we should endeavour to advance in biological knowledge, which alone can free us still further from the evils of disease."

BORNHOLM DISEASE IN THE TROPICS

BY

W. M. JAMESON, M.D., D.P.H.

Formerly Wing Commander, Medical Specialist, R.A.F.V.R.

AND

D. M. PRINSLEY, M.B., B.S.

Formerly Squadron Leader, Medical Officer, R.A.F.V.R.

An outbreak of Bornholm disease occurred at Aden in the late hot season of 1946. Between Aug. 17 and Oct. 25 we saw 35 cases. This malady has at various times been reported from Northern Europe, U.S.A., Britain, Southern Australia, and more recently from Egypt. So far as we are aware only one previous outbreak of the disease has been reported in the Tropics (McDaniel, 1944), although conversation with Service colleagues has indicated that it is not unknown in parts of tropical India and in Singapore. Aden, although a busy port of call on the East-West routes by sea and air, is nevertheless a relatively small and well-defined community, or rather collection of communities, and eminently suitable for studying an epidemic. All our cases were treated in the R.A.F. hospital, with the exception of two admitted to neighbouring sick quarters, two seen at their home (family of an R.A.F. officer), and one Arab taxi-driver who attended as an out-patient.

The same basic syndrome, with minor variations, has been described under many titles—"epidemic muscular rheumatism," "devil's grip," "epidemic myalgia," "Bornholm disease," "epidemic myositis," "epidemic pleurodynia," and "acute benign dry pleurisy." The condition is infective in origin and almost certainly primarily a lesion of the diaphragm, the exact nature of which is not clear. In view of this we have preferred to retain, for the present at least, the somewhat meaningless title first given to the syndrome by Sylvest (1934)—namely, "Bornholm disease."

With the exception of one case (the Arab taxi-driver) the outbreak was confined to personnel of the Services and their families. The age incidence, therefore, was such as might be expected from any condition affecting the Forces (Table 1). The incidence among officers and other ranks was: officers,

TABLE 1.—Age and Sex Incidence

Age:	0-10	10-15	15-20	20-25	25-30	30-35	35-40	40-45	45+	Total
Males	0	1	6	16	3	2	0	2	0	30
Females	0	1	0	1	1	1	1	0	0	5
Total	0	2	6	17	4	3	1	2	0	35

6; officers' families, 3; other ranks, 24; other ranks' families, 2. The ratio of British officers to other ranks in Aden is approximately 1:13. The relatively high incidence of the disease found in officers is thus in accordance with the Egyptian experience of Scadding (1946), who noted a "more common incidence among officers than among other ranks."

Clinical Features

Mode of Onset.—The onset was usually abrupt, with pain, headache, and some degree of fever as the most constant features. Only five cases suffered from upper respiratory tract catarrh, for periods varying between a few days and three weeks, before the onset of classical symptoms. Two cases had prodromal colic and diarrhoea, while a further two complained of lumbar backache for a few days previous to the attack. It is difficult to assess the significance of these various prodromata, since the commonest ailments seen in Aden are probably upper respiratory tract

infection, non-specific diarrhoea, and short-term fevers giving rise to various combinations of aches and pains.

The Pain.—The onset of pain was usually sudden and came on either at rest or after exercise. Thus one patient attributed his pain to the fact that he had spent an afternoon on the beach throwing stones. Another was seized with pain after riding, while several had been taking more violent exercise—for example, soccer and hockey. It seems most likely that these were all *post hoc ergo propter hoc*. As a rule the most acute pain was felt at the onset, although in a few cases (see below) an equally if not more severe attack was experienced in a recurrence. Two types of pain were observed. The first and most common was described as "sharp," "cutting," or "knife-like," while the second was of a constrictive nature, one patient saying that the sensation was like having "tight webbing strapped round the lower chest." The pain was always worsened by respiratory effort, as in deep breathing, coughing, and yawning, and even by movement in bed. The position of greatest comfort in bed varied. Quite a number preferred lying on the affected side, while an equal number preferred to lie flat on the back. A few cases achieved comfort from being propped up in bed, and some from lying on the sound side. The pain was felt along the right or left costal margin, in the epigastrium, or in various combinations of these sites. In a few cases tightness across the anterior chest was present. Two cases had no complaint of pain, but only a febrile upset consistent with the disease, and both developed orchitis in convalescence. The actual site of pain at the onset is shown in Table II. It will be seen from this table

TABLE II.—Distribution of Pain at Onset

Site of Pain	No. of Cases
Right costal margin	6
Left	4
Epigastrium	8
Right and left costal margin	4
Right costal margin and epigastrium	3
Left	3
Right and left costal margin and epigastrium	Nil
Tightness, anterior chest	2
Febrile upset only " + epigastrium	3
Febrile upset only	2
Total	35

that there was no particular predilection for any one of the sites usually involved. Spread of pain was observed in 11 cases. Of these, eight showed final involvement of both costal margins and epigastrium, while two showed spread from the epigastrium to one side, and one from one side to the epigastrium. Referred pain was relatively common, being present in 11 cases. In several instances this was actually more severe than the pain around the lower chest. The sites affected were: shoulder-tip (bilateral), 3 cases; shoulder-tip (unilateral), 5; interscapular, 2; umbilicus to groin, 1 case. The shoulder affected was in direct relation to the side of the lower chest affected. The duration of the pain is given in Table III. It will be seen that 24 of the 33

TABLE III.—Duration of Pain in Days

Days:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	23
Cases:	—	4	8	2	4	1	5	—	2	—	2	1	—	1	1	—	1	1

cases were entirely free from pain in from two to seven days. The longest recovery time was 23 days. It should be noted that these times are for *complete* clearance of the pain. Exacerbations were of frequent occurrence, but there was no real instance of relapse. In several cases the initial pain had almost, but never entirely, disappeared before recurring in an equally and sometimes more severe form.

Headache.—Headache was present in 18 of the 35 cases. In 11 it occurred at the onset, while in the remaining seven it came on in from two to seven days. The post-onset headaches were always more severe than the others, and almost amounted to a definite complication. The pain was excruciating, being frontal in three instances and generalized in four. In one case (D. M. P.—see below) the headache was associated with signs of meningeal irritation and was severe enough to warrant lumbar puncture. The cerebrospinal fluid, although showing a very slight increase in pressure, was normal in every other respect. The duration of the headache in its severe phase varied from one to four days, but occasionally the patient was left with a "heaviness" or dull ache for several days longer.

Pyrexia.—With one exception every case was pyrexial at the onset. Twenty-two had temperatures not exceeding 100° F. (37.8° C.), seven between 100° and 102° F. (37.8° and 38.9° C.), and five over 102° F. The highest temperature noted was 105° F. (40.6° C.), but the higher temperatures were never sustained beyond a single recording. The chart usually showed a fairly rapid return to normal, 28 cases being normal within four days, 32 within seven days, and 34 within 12 days. The pulse rate for the most part was in accordance with the temperature.

Sore Throat.—Fourteen patients complained of soreness of the throat in the initial phase. All of these presented a generalized inflammation of the fauces without exudate. Throat swabs were examined in six of these, with the following cultural results: *Staph. albus*, 1 case; *Staph. aureus*, 1; non-haemolytic streptococcus, 1; haemolytic streptococcus and *Str. viridans*, 1; *Staph. albus*, non-haemolytic streptococcus, and *Str. viridans*, 1; no growth, 1. Throat swabs were also examined in six cases without sore throat, the result being: *Staph. albus* and non-haemolytic streptococcus, 3 cases; non-haemolytic streptococcus, 2; *Staph. albus*, 1 case.

Other Symptoms.—Anorexia was fairly common (21 cases). Nausea was present in two cases, vomiting in one. In two cases cough with sputum was troublesome in the acute phase. Pain in the lower limbs was observed in one case. The bowels showed no great change from the normal, diarrhoea being present in six cases, constipation in five.

Physical Signs.—Examination of the chest revealed no abnormal signs, except in one case in which a very distinct pleural rub developed on the sixth day of the disease and lasted for eight days. The rub was unusual both in its intensity and in its wide distribution over the chest, and it could be demonstrated by palpation as well as by auscultation. It seems probable that it was due to a super-added fibrinous pleurisy. Repeated clinical and radiological examination showed no signs of any effusion. Subcostal tenderness was present in 16 patients—unilateral in 10, bilateral in three, and epigastric in three. Upper abdominal guarding and rigidity were noted in only four cases. Cutaneous hyperaesthesia was not a feature of this outbreak, but was observed in four cases. It was localized to the costal margin and corresponding lower part of the chest.

Radiological Findings.—X-ray films of the chest were taken in 25 of the cases, while 21 were screened in the acute phase of the illness. The diaphragm was freely mobile in every case, and no abnormality was found in the lung fields.

Haematology.—Twenty-four cases were subjected to blood examination, comprising red cell count and haemoglobin estimation, white cell and differential count, and erythrocyte sedimentation rate. The red cells varied between 4.2 and 5 millions per c.mm. and the haemoglobin between 80% and 100% (Sahli). The colour index was

invariably around 1. There was no abnormality in the red cells, and no abnormal cells were present. These findings are in accordance with those obtained in healthy persons in Aden. The white cell counts were: Under 8,000 per c.mm., 2 cases; 8,000-10,000, 10; 10,000-12,000, 10; 12,000-13,000, 2. Differential counts showed that any increase in cells was in the polymorphonuclears. Lymphocytes, monocytes, and eosinophils showed no departure from normal. The erythrocyte sedimentation rates (Westergren method) in the acute stage of the illness were:

0-15 mm. in 1st hour	No. of Cases
15-20	5
20-30	4
30-40	6
40-50	2
50-60	4
60-70	1

The erythrocyte sedimentation rate, noted at weekly intervals, showed a return to normal in periods varying between seven and 21 days, thus revealing a very distinct lag behind clinical clearance. In the cases developing orchitis in convalescence (see below) a distinct rise in the E.S.R. was noted in six instances, while in a further six the progress of the E.S.R. to the normal figure was uninterrupted. (Note: 0-15 mm. in the first hour was regarded as a normal figure for men in Aden.) Blood culture was carried out in only one case. The culture remained sterile.

Complications.—Orchitis was by far the most outstanding complication, occurring in 12 of the 30 male cases. It was always unilateral, and affected the right and left sides equally. There was usually an accompanying mild febrile reaction. The day of disease on which the orchitis developed is shown in Table IV. The orchitis cleared for

TABLE IV.—Development of Orchitis in Relation to Day of Disease

		Day of Disease												
		1-7	8	9	10	11	12	13	14	15	16	27	39	
No. of cases	..	—	1	—	1	—	3	1	—	—	4	1	1	

the most part in two to six days, only one case lasting as long as 10 days. There was no apparent corresponding ovaritis in any of the female patients. Headache developing after the onset was, as already stated, of such intensity as to be classed as a complication, and was present in seven cases. Actual encephalitis or meningo-encephalitis, which has been reported in other outbreaks, was not observed by us. Pleurisy has also been described as a complication. One case (see above) developed a marked pleural rub, which we considered to be due to a fibrinous pleurisy. Physical signs disappeared in eight days and x-ray findings were normal.

A Personal Account of the Disease

One of us (D.M.P.) developed the disease, and it is considered worth while to include his personal account of the illness.

"The first sign of illness was noticed in the morning of Sept. 2, 1946, when upper abdominal pain commenced. The pain was quite localized in the central epigastrium; it was of a constant aching character and slowly progressive in severity, aggravated by movement as a whole. By 2 p.m. there was so much discomfort that I was unable to walk about, had no appetite, and felt ill. Aspirin was taken without effect. By 6 p.m. the pain had moved to the right costal margin and was definitely affected by movements of the diaphragm. There was also a constant aching sensation in the right shoulder-tip. The temperature was 101.8° F. (38.8° C.). A slight irritating cough appeared and there were the usual pyrexial symptoms of headache, giddiness, etc. Later that night there was a short rigor

followed by profuse sweating. Sleep was impossible owing to general discomfort.

"The next morning the temperature was 103.8° F. (39.9° C.) and the pain was severe in the right lower chest and back. There was marked cutaneous hyperaesthesia of the anterior chest and upper abdomen. During the day the temperature fell to 101.8° F. (38.8° C.) and pain subsided, being noticeable only in the lumbar region. On Sept. 4 I felt perfectly well again. My appetite returned, the cough disappeared, and apart from slight backache there was no discomfort. The temperature was normal.

"In the early hours of the 5th the pain in the right side of the chest returned, exactly the same as before. The temperature was 99.4° F. (37.4° C.). By midday the pain in the right side ceased and was replaced by a similar pain in the left lower chest, with aching in the left shoulder-tip, and aggravation of the symptoms occurred with diaphragmatic movements. By 2 p.m. the temperature was 101° F. (38.3° C.), and the pain, particularly in the left shoulder area, was very severe. A hypodermic injection of morphine, 1/4 gr. (16 mg.), gave relief. At about 8 o'clock the same night headache over the vertex began. It was quite the worst headache I have ever experienced, and lasted until the middle of next day. Recovery started on Sept. 7 and was uneventful apart from persistent right-sided headache and vague right chest pain, which lasted for a further week."

Physical examination revealed no abnormal signs other than tenderness, present at first in the epigastrium and along the right costal margin, and later along the left costal margin. X-ray examination and screening of the chest showed no abnormality. *Staph. albus* and a non-haemolytic streptococcus were cultured from the throat. On Sept. 9 the E.S.R. was 21 mm. in one hour and the total white cell count 12,000 per c.mm. (78.1% neutrophils). On Sept. 18 the E.S.R. was 7 mm. in one hour and the total white cell count 10,200 per c.mm. Lumbar puncture on Sept. 6—that is, at the height of the headache—showed the cerebrospinal fluid to be completely normal.

Treatment

Treatment was performed symptomatic. The milder analgesics such as codeine and aspirin were largely used and found of some value. Likewise the salicylate group of drugs often gave relief, and these combined with a nightly barbiturate became the routine line of treatment, with the hypodermic injection of morphine, 1/4 gr. (16 mg.), reserved for especially severe cases. The patient was made comfortable in bed in the position he himself chose, and he had what he wished to eat. The appetite usually recovered quite quickly. The headache was often of such severity as to justify the prescribing of morphine. Orchitis was treated simply by rest in bed and the use of a suspensory bandage.

Differential Diagnosis

In its epidemic form Bornholm disease is unlikely to be confused with other conditions, but sporadic cases or cases occurring at the start of an epidemic may give rise to considerable difficulty.

(a) *Pleurisy* has obviously to be considered, but the unilateral nature of this condition, together with the absence of chest signs in Bornholm disease, is usually sufficient differentiation. Scadding (1946), however, detected a pleural rub in 11 of his 20 cases, and indeed used the name "acute benign dry pleurisy" for the disease.

(b) *Upper abdominal emergency* has been reported as being simulated by Bornholm disease. Although a few of our cases presented upper abdominal tenderness and muscular guarding there was never any great difficulty in deciding that the case was not an acute abdomen.

(c) *Infective hepatitis* in the pre-icteric stage can give rise to real difficulty. Here we have an illness characterized by pain, tenderness, and sometimes muscular guarding below the right costal margin, by pyrexia, and by general upset. The pain, however, has never the same relation to respiratory effort, and nausea and vomiting are much more constant. The development

of jaundice and the presence of bile in the urine about the fourth to seventh day finally clinch the diagnosis.

(d) *Malaria* was an occasional difficulty, especially those cases showing pyrexial symptoms with pain in the left side and tenderness on palpation below the left costal margin without obvious splenic enlargement. The practice of examining blood films for malaria parasites in all cases of pyrexial illness usually, but not always, provided the answer.

Epidemiology

The outbreak reported here occurred in the late hot season in Aden, and the weekly incidence of cases, in terms of onset, is shown in Table V. A study of meteorological charts revealed no significant climatic changes from previous years.

TABLE V.—Weekly Incidence of Cases (in terms of onset)

Week ending	No. of Cases	Week ending	No. of Cases
Aug. 23	3	Sept. 27	3
" 30	3	Oct. 4	1
Sept. 6	9	" 11	0
" 13	7	" 18	1
" 20	4	" 25	1

The causal agent has never been discovered. The clinical picture, the nature of the complications, and the failure to demonstrate any constant bacterial agent suggest a virus infection, although the mild leucocytosis encountered invariably showed an increase in the polymorphonuclears. The mode of spread, too, is somewhat vague. The various modes postulated have been direct by droplet infection and indirect by infected water, infected food, or insects. In Aden there are several well-defined communities. These include the British Services, Indian Services, European civilians, Indian civilians, and the local native population (chiefly Arabs and Somalis). As previously stated, the outbreak was confined to the British Services, with the exception of the single case in an Arab. The water supply is derived from deep wells and is very pure. It is examined bacteriologically at regular intervals at many points and has always been satisfactory. Moreover, the supply is common to the entire population, and it is difficult to conceive why, if the infection were water-borne, virtually the Services alone should be affected. The native population use goats' milk chiefly. The Europeans use cows' milk, drawing their supplies from two main sources—a civilian dairy-farm and a Services dairy-farm—but there is considerable interchange between the two. No cases of the disease occurred in the staffs of the respective dairies, and bacteriological examination of the milks was satisfactory at the time of the outbreak. Food-borne infection was considered, since food supplies to the British Services, civilians, Indian Services, and natives were all from different sources. An interesting feature in this respect was seen in one camp where a unit of Cingalese troops were living in proximity to an Indian unit. The Cingalese were on British Service rations, while the Indians had their own special dietary. Two of the Cingalese detachment developed the disease, while no cases occurred among the Indians. It must be stated, however, that in spite of the close proximity of these units there was practically no "mixing" between the two. Another most interesting fact was that while the medical staff of the Indian hospital in Aden saw no cases of Bornholm disease, they did have an outbreak of mumps among Indian personnel at that time. The R.A.F. and civilian authorities did not have a single case of mumps. The importance of this will be realized when one states that the Indian authorities had several cases admitted with orchitis which they presumed, in view of their epidemic, to be complications of "missed" cases of mumps. Insect-borne disease is unlikely, since Aden is comparatively free from most of the usual pathogen-carrying insects.

While infection conveyed by milk or food cannot be excluded, it seems more likely that the spread is direct by droplet infection. The disease is known to occur in Egypt (Scadding, 1946), and Aden is reached in less than 24 hours from there by the usual air route, thus making the introduction of infection, even with the shortest incubation period, easy. There is surprisingly little "mixing" between Service and civilian personnel in Aden, so that an epidemic in one would not necessarily pass readily to the other. The case of the Arab taxi-driver may be significant, for he was a native, having his own particular diet including goats' milk, who developed the disease in a fairly severe form. Droplet infection would seem the most obvious mode of spread in this instance. There was one example of family infection—an R.A.F. officer, his wife, and two children—all developing the disease at varying times within eleven days. At the height of the outbreak five of the hospital staff, including one medical officer, one nursing sister, and three nursing orderlies, all in close contact with cases developed the disease. Furthermore, one patient, who was in hospital with a left-sided pleural effusion for about three months, contracted Bornholm disease affecting chiefly the right side and complicated by the later development of orchitis. He had been nursed in a general ward which included several cases of the disease, and was almost certainly cross-infected. Lastly, the incidence of faucial inflammation at the onset in 14 cases would seem to lend support to the view that the mode of spread is direct from case to case by droplet infection. The incubation period appears to be a short one. Huss (1934) found it to be about four days, and such evidence as we had agreed with this finding.

Summary

An outbreak comprising 35 cases of Bornholm disease occurring in Aden in the late hot season is described.

The clinical picture, with minor variations, approximated to the classical syndrome.

Blood examination showed only a slight polymorphonuclear leucocytosis and a raised E.S.R.

Radiological examination showed no deviation from normal.

Orchitis was the most outstanding complication, being present in 12 of the 30 male cases. Dry pleurisy complicated one case, while headache of such severity as to be classed as a complication was present in seven.

The epidemiology is discussed. Direct droplet infection is considered the most likely mode of spread, although food or milk-borne infection cannot be excluded.

Our thanks are due to Group Captain G. P. O'Connell for permission to publish this report; also to Flight Sergeant P. Gaul for his technical assistance with the laboratory work.

The beliefs and rituals of primitive races, by their remoteness from our experience, the obscurity of their significance, and their monotony, are sometimes dull to read about to any but anthropologists; the beat of distant drums, exciting at first, falls on soon-tired ears. Mr. Lewis Litt, in *Savage Tales* (Wadley and Ginn, Dominion House, Bartholomew Close, London, E.C.1: 8s. 6d.), has adopted the form of the short story and used it with considerable imagination to record the myths and customs of some of the Papuan tribes. From many years' experience of living among them he has acquired a remarkable facility at penetrating the native mind and reveals its passions, fears, and aspirations in the setting of the natives' daily life and as part of the characters of individual men and women. His book is the more valuable in that he records in an attractive manner a way of life that is gradually disappearing as the white man's civilization encroaches upon it. The opportunities for intimate contact with the Papuans that he has enjoyed will never recur.

A NOTE ON THE CAUSATION OF SUDDEN DEATH

BY

ROBERT RICHARDS, M.D., F.R.C.S.Ed.

Lecturer in Forensic Medicine, University of Aberdeen

One of the duties of a procurator-fiscal in Scotland is to investigate all cases of death from any form of violence, as well as all sudden deaths and deaths from unknown or suspicious causes. In most cases this is done by private inquiry—though provision is made by statute for fuller inquiry into certain deaths from industrial accidents and other causes—a procedure possessing certain advantages over the coroner's inquest. Part of the procedure initiated by the procurator-fiscal is an examination of the body by the casualty police surgeon, with or without a necropsy, and this note is based on an investigation to elucidate the cause of 1,694 cases of sudden, violent, and suspicious death from 1931 to 1945.

These cases fall into two groups—those in which the actual cause was definitely ascertained post mortem (572) and those in which external examination alone was carried out (1,122). From the former I have deducted 45 cases of newly born children, many of them stillbirths, or non-viable foetuses. On the other hand, many cases of suicide were not subjected to post-mortem examination because the cause of death was obvious—hanging, gunshot wound, cut throat, etc. In suicide, wherever there was doubt as to the cause, a necropsy was done; so all suicides are added to the number of cases where the cause was definitely ascertained. This gives a total of 823 (post-mortem cases (572 less 45), 527; cases of suicide not coming to necropsy, 296), or nearly one-half the total cases, over a period of 14 years. An analysis of these is detailed below.

Non-violent Group

Of the 823 cases 200 were due to non-violent causes, with the addition of 24 cases of infants under 2 years which have been considered separately because of a tendency to certain special types of death they exhibit. The remaining 599 were due to external agencies, suicide accounting for 365 cases and other external causes (accidental or intentional) for 234. The non-violent group consisted of:

	Cases	Infants
Deaths due to cardiovascular degeneration ..	104 (52%)	
Deaths due to diseases of the respiratory system ..	26 (13%)	17
Deaths due to diseases of the nervous system ..	33 (16.5%)	2
Deaths due to diseases of the gastro-intestinal system ..	15 (7.5%)	
Deaths associated with pregnancy ..	9 (4.5%)	
Other causes ..	13 (6.5%)	5
	200	24

Diseases of the Cardiovascular System.—The cardiovascular cases—104 (52% of the total)—form much the largest group, though not so large as in some previously reported lists of causes of sudden deaths. They were grouped as follows:

Coronary atheroma and thrombosis ..	51	} 39.5% of total
Rupture of heart ..	3	
Myocarditis—fibrous or fatty ..	25	
V.D.H. ..	4	
Intracerebral haemorrhage ..	13	
Ruptured aortic aneurysms ..	6	
Pulmonary embolism ..	2	

The first three groups may be considered together. Many cases showed gross atheromatous changes of the coronary arteries, so that these could only with difficulty be cut with a knife; others showed localized atheromatous changes in the arteries, and still others only small isolated plaques—

in all causing such narrowing of the lumen that in some an acute cardiac ischaemia and death, probably from ventricular fibrillation, resulted and in others the narrowed area formed a nidus for thrombus formation and cardiac infarction. If death did not occur at once it might follow in a few days from rupture of the heart through the softened area supplied by the thrombosed vessel, as in the three cases mentioned. Cases showing temporary recovery resulted in myocardial changes, diffuse or localized, with impaired cardiac function. In four cases this fibrosis resulted in a cardiac aneurysm, but in no instance did this rupture. Included in this group are four cases of gross enlargement of the heart which on section showed fatty degeneration of the muscles. One case of coronary embolism was seen in which there were many vegetations on the aortic cusps and a raw area where one of these had become detached; it was found plugged in the right coronary artery, and was about the size of a grain of rice. In four others the main lesion was valvular—two mitral stenosis and two aortic stenosis and incompetence. These also showed evidence of fibrosis of the myocardium. There were 13 cases of cerebral haemorrhage (apart from subarachnoid haemorrhage), and all of them gave evidence of arteriosclerosis with concomitant enlargement of the heart. Eight showed that the haemorrhage arose in the neighbourhood of the internal capsule and five were cases of pontine haemorrhage. Possibly the more rapid termination in cases of pontine haemorrhage resulted in a greater proportion of those being investigated as sudden deaths than in the ordinary cases, which are usually seen by a doctor before death occurs. Of the six cases of ruptured aneurysm three were saccular aneurysms of the aorta; the other three were dissecting aneurysms arising from atheromatous ulceration. Of two cases of pulmonary embolism which came to necropsy one resulted from a thrombosis of varicose veins extending into the iliac veins; the other followed 10 days after a confinement.

Diseases of the Respiratory System (26 Cases).—Of these deaths 19 resulted from pneumonia, mainly of the fulminant influenzal haemorrhagic type, which in two cases caused death within four hours of apparent onset; two were due to bronchiolitis and one to status asthmaticus. Four were the result of haemorrhage from tuberculosis, death being due to asphyxia from intrabronchial clotting rather than to the actual blood loss.

Diseases of the Nervous System (33 Cases).—Cases of subarachnoid haemorrhage form more than one-third of this group. In only a few was it possible to demonstrate the actual congenital aneurysmal dilatation of the vessel—though it is interesting to note the finding of an unruptured aneurysm the size of a hazel-nut in a case in which death was due to violence. The youngest subject in this series was 10 years and the oldest 59. The following table shows the usual age distribution of cases of this type.

	Present Cases	Magee's 150 Cases
Under 20 years ..	3	9
20-30 ..	1	76
30-40 ..	2	56
40-50 ..	5	9
Over 50 ..	2	—

Six cases occurred in asylum inmates and were due to exhaustion from acute mania, five were cases of cerebral softening from cerebral thrombosis, and three were brain tumours with acute oedema of the brain. There were three cases of fulminant cerebrospinal meningitis—two in brothers who took ill within two days of each other, each dying after less than one night's illness. The third died after eight hours' illness and showed the typical

Waterhouse-Friderichsen syndrome with gross haemorrhage into both adrenals. Of the others, one was a case of general paralysis of the insane in which death was due to idiosyncrasy to arsenical drugs, one of status epilepticus, and one of hydrocephalus.

Diseases of the Gastro-intestinal System (15 Cases).—Acute perforations accounted for nine cases, intestinal obstruction for four cases. One case resulted from haemorrhage from a gastric ulcer, and one from colitis which suggested mercurial poisoning, but all analyses were negative.

Diseases Associated with Pregnancy (9 Cases).—Four of these resulted from toxæmias of pregnancy; four were the result of abortions—three from sepsis and one from air embolism; and one was an ectopic gestation.

Other Causes (13 Cases).—The only interest of these 13 cases lies in one case of Addison's disease, two where starvation was the cause, and two others where in the presence of lymphatism and absence of any other apparent cause the deaths were attributed to status lymphaticus.

Infant Cases.—In addition to the 200 cases above listed there were 24 post-mortem examinations on infants. These have been kept separate because the majority of these are of one type. The usual history is that a young child is put to bed after a feed, either apparently quite well or with only a mild catarrhal cold, and in the morning is found dead in its cot. These infants are frequently proved to have died from pneumonia. A dramatic occurrence was in twins 4 months old. Twin A had a very mild cold the previous day, and there was no history of any further illness. Twin B had no history of illness at all. At 8.30 a.m. the mother tucked both children in their cot, apparently well, and went to her washing-house to soak in her clothes. On her return at 9.30 both twins were dead. At necropsy both were found to have had pneumonia, Twin A in a more advanced stage than Twin B. Of the 24 cases in this group 12 had pneumonia: four were due to asphyxia, probably overlaying; two to cerebrospinal meningitis; one to a hepatoma, and one to total infarct of the kidney. The other four were one case each due to cerebral haemorrhage (from labour), colitis, bronchitis, and status lymphaticus.

Deaths due to External Agencies

This group of deaths, numbering 599, occurred from the following causes:

Suicides (necropsy)	69
Suicides—examined externally only	296
Injuries, wounds, and burns	150
Associated with anaesthetics	32
Asphyxias, drowning, strangulation, etc.	21
Poisonings	20
Other causes	11

Suicides (365 Cases).—It will be seen that suicides form a large proportion of the total. The interest of this group lies in the method chosen and in the evidence of imitation in the recurrence of similar methods of self-destruction about the same time, especially noticeable in the coal-gas and precipitation groups. "How oft the sight of means to do ill deeds makes ill deeds done." The following is an analysis of the methods adopted:

Coal-gas	144 (40%)	Hanging	14 (3.8%)
Drowning	123 (33.6%)	Cut throat	14 (3.8%)
Poisoning	37 (10.2%)	Gunshot wounds	12 (3.2%)
Precipitation	18 (4.9%)	Trains	3 (0.8%)

As is usually seen, coal-gas provides the majority of cases, though cases of drowning approach the same figure, perhaps from the proximity of harbour, sea, and rivers in the area. Of the 37 cases of poisoning, lysol caused 18, again illustrating the usual habit, 11 were due to narcotics (barbiturates, chloral, bromides, and chloroform), three to prussic acid (occurring in two chemists and a laboratory

attendant), two to corrosive sublimate, and one each arsenic, strychnine, and aspirin. The other types of suicide for no comment.

Deaths due to Injuries and Wounds (150 Cases).—These generally are of little pathological interest. Head injury was responsible for 90, rupture of organs for 28, multiple limb injuries for 12, and fracture of the spine for 6; in all the cases in these groups were caused by motor accidents.

Deaths Associated with Anaesthetics (32 Cases).—Of these cases 17 could be attributed directly to the disease which created the necessity for operation or to post-operative shock—for example, gangrene of leg, two cases (one with aortic thrombosis); cancer of breast and stomach, uterus, and prostate; toxæmia from pelvic abscess and gangrenous appendicitis; and post-operative haemorrhage from a venous cyst and from gastrectomy. Of the cases where the anaesthetic played a major part in the cause of death three followed the inhalation of blood in throat and nose cases and two from the inhalation of vomit. One was a case of circumcision with status lymphaticus and one with hydrocephalus which collapsed on being given 1/2 (14 ml.) of ether for the purpose of taking an encephalogram. In six cases—two of tonsillitis, one of mastoiditis, one tuberculous nodes of the neck, one of antral suppuration and one for the change of a plaster casing—the anaesthetic alone appeared to be responsible for the collapse. Three cases followed the application of a 2% amethocaine hydrochloride (decicain) spray—one a tumour of the lung and the other a case of bronchiectasis. The anaesthetic was given to permit of a bronchoscopy, and in both cases generalized convulsions set in within a few minutes and death occurred very shortly afterwards.

Deaths from Poisoning (21 Cases).—Six of these were accidental deaths from carbon monoxide from stoves (coal-gas); seven were the result of asphyxia in alcohol coma; four were caused by drinking the synthetic methanol; and one each from phosphorus (rat paste used as an abortifacient), hydrocyanic gas (in a ship fumigator), quinine (also used as an abortifacient), and lysol applied externally as a dressing in mistake for eusol.

Asphyxias, Drowning, etc. (20 Cases).—These include 11 cases of accidental drowning, one accidental strangulation and four cases of choking on foreign bodies—two in lunatics (a bun and an oatmeal pudding being the offending agents) and two in children from a bean and a particle of food.

Other Causes (11 Cases).—Of the 11 cases so classified two resulted from tetanus, two from pyæmia, and two from septic abortion. One case of oedema of the glottis occurred in a schoolboy who was kicked on the neck in a game of football and died within 20 minutes.

An interesting feature of this group is that in 16 of these cases of death from all classes of violence a charge of murder or culpable homicide followed. Three were in children murdered by an insane mother by coal-gas; three were head injuries; three resulted from strangulation—two manual and one with a handkerchief; two from cut throats; and one each from fracture of the spine, stabbing, shot-gun wound, and lysol—this last in a child murdered by its mother, who also committed suicide with lysol.

Cases Not Examined Post Mortem

Of the 1,122 cases in which external examination alone was carried out, 296 suicides have already been dealt with; 12 others related to newly born children and are discounted for reasons previously stated. This leaves 814 cases, of which 404 were cases of sudden death, 305 cases of injury, etc., and 105 infant cases. In a great number the cause of

death was not conclusive, so it is undesirable to base any conclusions on the figures; but experience of large numbers of these cases allows an examiner to group the probable causes of death with reasonable accuracy for registration purposes.

Cases of sudden death	404 cases
Cardiovascular group	357
Respiratory diseases	21
Nervous system diseases	8
Gastro-intestinal diseases	3
Miscellaneous causes	15

Here the outstanding feature is the proportion of deaths (85%) attributed to cardiovascular causes. This is not surprising when one considers that most of these were of people collapsing in the street or at work, or found dead in bed. In ordinary times many of these cases would have come to necropsy, but as nearly half occurred during the war years, when post-mortem examinations were reduced to a minimum, they were ascribed to the most likely cause as adjudged from the previous history and mode of death. In all, 318 deaths were thus considered to be due to coronary thrombosis and myocarditis; 11 to valvular diseases; 22 to cerebral haemorrhage; one to ruptured aneurysm, and five to pulmonary embolism.

Deaths from External Agencies (305 Cases).—These deaths were due to the following causes:

Injuries:	
Fractured skulls	101
Ruptured organs	25
Fractured limbs and spine	25
Burns	14
Exposure	2
Other causes	4
Drowning	70
Accidental carbon monoxide asphyxias	22
Associated with anaesthetics	36
Poisons	6

The first point of interest here is the comparison of the accidental deaths from inhalation of carbon monoxide—22 cases plus six that came to necropsy, 28 (16%) in all—with the 144 (84%) such cases due to suicide. The six poison cases were all due to alcohol. Nearly all of the 36 deaths associated with anaesthetics were due to the condition necessitating anaesthesia or to post-operative shock or haemorrhage—hence necropsy (especially in the war years) was not done. For example, 13 were cases of malignant disease and 7 were abdominal emergencies. Three special cases may be noted: one of tetanus which ended in death during a spasm while receiving chloroform; another that of a child of 23 months with a tuberculous lesion of the skull who received 40 ml. of a 0.5% solution of "novocain," followed by a nitrous oxide, oxygen, and ether anaesthesia, in which the local anaesthetic was certainly in excess of a safe dosage; and a third case, that of a man suffering from a deflected septum who had this treated locally with a swab of adrenaline dipped in cocaine crystals and died in convulsions within a few minutes, presumably from poisoning by cocaine owing to idiosyncrasy to the drug.

Infant Cases.—The 105 infant cases show the same tendency as the post-mortem cases: 55 were regarded as due to respiratory causes—50 to pneumonia and 5 to bronchitis—21 were asphyxial deaths, mostly accidental overlaying; 13 were due to convulsions, nine to prematurity, and five to acute infections—measles (three) and whooping-cough (two).

Conclusion

Exact inferences may not be drawn from the figures given, but there seem to be three points which deserve some emphasis: (1) the outstanding predominance of cases of cardiovascular degeneration as a cause of sudden death—461 (76%) out of 604 cases; (2) the frequency of coal-gas as a suicidal agent; and (3) the frequency of pneumonia (50%) as a cause of sudden death in young infants.

HEMIPLEGIA IN YOUNG ADULTS

BY

G. JOLY DIXON, M.A., M.D., M.R.C.P.

Strokes in the elderly are usually regarded as a manifestation of cerebral vascular disease, while in the young adult they are usually thought to be due to some extraneous cause. The purpose of this paper is to emphasize both the obscurity of aetiology and the frequency of strokes in young adults.

The cases selected for study are all instances of unilateral pyramidal palsy seen in Service personnel between the ages of 20 and 40 at the E.M.S. Neurological Centre, Winwick, between 1940 and 1946, and also four civilians of the same age group admitted to the Warrington General Hospital between 1944 and 1946; in all 35. Nineteen of these patients had only minor degrees of hemiparesis, and in these a convincing cause was found. Thus, seven occurred among 30 consecutive cases of cerebral tumour, six among 30 consecutive cases of disseminated sclerosis, three cases of congenital hemiparesis had been accepted by the recruitment board, and two cases of hysteria and a hemiparesis due to syringomyelia completed the total. It so happened that the onset of the palsy in all these 19 patients was insidious.

The remaining 16 patients with more severe palsies all had a sudden stroke; of these, two men suffered cerebral emboli during the course of rheumatic mitral stenosis with pulmonary infarcts (Case 20) and bacterial endocarditis (Case 21). Another in retrospect presumably had suffered a Herxheimer reaction during the treatment of secondary syphilis (Case 22); a fourth must have had a cerebral aneurysm, as his stroke occurred 10 days after a sub-arachnoid haemorrhage; and a woman (Case 24) aged 29 developed a hemiplegia whenever an overdose of insulin was administered in treatment of her diabetes mellitus. A case similar to this last was described by Fischer and Florman (1943), though their patient eventually suffered from a cerebral embolus. It is of interest that Case 21 eventually recovered from the endocarditis after treatment with penicillin, though he was left with an almost useless left hand and spastic leg and auricular fibrillation; while Case 22 recovered sufficiently to be conscripted three years after his stroke.

Eleven of the severely palsied cases were not so readily diagnosed. Of these, two convalescent Service men (Cases 25 and 26) who had no pyramidal signs were at first labelled hysteria; however, they both claimed unilateral loss of sense of position and a field defect on the same side. An almost identical Service case was described by Stewart, Randall, and Riesenman (1943) and diagnosed by them as hysteria. However, in reconsidering these three patients it appeared remarkable that all of them should have mimicked so closely the symptomatology of a vascular lesion in the posterior portion of the internal capsule, and when Case 25 was re-examined two years later the signs were unaltered, except that he had developed choreiform athetotic movements of the affected shoulder and a pneumocephalogram demonstrated localized cortical atrophy. Six months after his stroke Case 26 wrote that his condition was stationary. It seems possible that had the frequency of strokes in young adults been appreciated at the time both Cases 25 and 26 would have been differently labelled.

Three of the cases under review had sepsis in the jugular vascular bed on the same side as the brain was affected—namely, in Case 27 a tuberculous gland on the right side of the neck, in Case 28 a Vincent's ulcer on the left tonsil, and in Case 29 a right-sided chronic otitis media. Dowman

(1926) and Purdon Martin (1944) have described strokes in this age group due to cerebral venous thrombosis, and Symonds (1937, 1940) has stressed the importance of sepsis in the middle ear and nasopharynx as a cause of thrombophlebitis of the Rolandic veins. Another soldier (Case 30) gave a history of an unexplained femoral phlebitis six years previously, and at the time of his stroke he was under investigation for an obscure painful lesion in the left lung.

Elkington (1935) described the cases of three young adults whom he concluded to be suffering from cerebral haemorrhage because of the site of the lesion, the suddenness of the onset, and the finding of slightly xanthochromic fluid on lumbar puncture in two who had no other signs of subarachnoid haemorrhage. He compared them with a woman of 27 who died from a pontocerebellar haemorrhage resulting from telangiectasis in this region and another woman, described by Gordon Holmes (1931), who developed a left homonymous hemianopia from an arteriovenous aneurysm in the calcarine fissure. The cases here examined resembled Elkington's in the sudden onset and the site of the lesion, and resembled other vascular accidents in the fact that their condition has changed very little during the period of one to four years they have been under observation. However, abnormality of cerebrospinal fluid was a rarity. Case 25 had a slight increase in globulin and a gold curve of 1221110000, and Case 31 had seven lymphocytes per c.mm. in the cerebrospinal fluid.

It seems probable that Case 31 had a cerebral haemorrhage, as at the time of his stroke he suffered a transient glycosuria and albuminuria. This patient, a soldier aged 30, is of interest as two months previously he had suffered from infective hepatitis. Lescher (1944) and Stokes, Owen, and Holmes (1945) describe four cases of cerebral haemorrhage complicating this disease. In Lescher's case the same time interval occurred as in Case 31. The neurological signs in Case 31 were consistent with a lesion in the right internal capsule, but this lesion was presumably more extensive, as he developed epileptiform convulsions and a pneumo-encephalogram seven months after the stroke showed extensive atrophy of the right cerebral cortex. Stokes *et al.* in describing the necropsy of their Case A state: "The brain contained an area of softening lateral to the right lateral ventricle and a large haemorrhage into the right caudate nucleus." Had this patient survived he would presumably have presented an almost identical clinical picture to Case 31, except for the site of the palsy.

No other patient showed evidence that the vascular atrophy was due to haemorrhage. One patient at least, a housewife aged 26, presumably had a cerebral embolus, for on admission she was found to have a cloudy wedge-shaped area lying on either side of a pair of vessels in the upper temporal sector of the left retina. These vessels were somewhat obscured near the disk; peripherally, the artery was seen to be empty and the vein normal. It is suggested that this woman's sudden loss of consciousness the day before admission had resulted from an embolus which had broken up in the left internal carotid artery. The smaller part lodged in the retina and the larger part occluded branches of the left middle cerebral artery. The patient had prolonged unconsciousness, which after about ten days gave place to complete aphasia, right-sided spastic paralysis of face, arm, and leg, and loss of sense of position in these limbs. Later, absence of the nasal field was demonstrated in the right eye, presumably due to the local lesion in the retina.

None of these nine obscure cases had any abnormality of the urine, and the cardiovascular systems appeared healthy except that in three Service men when stress was shown during examination a high blood pressure was found

(150/100 in Case 25, 150/100 in Case 26, and 140/100 in Case 31), normal pressures being recorded at other times in these patients. Another associated finding was recent evidence of pulmonary disease; thus, Case 25 was at the time of his stroke convalescent from pneumonia, and Case 31 during the month preceding his stroke had had three attacks of left-sided pleurisy and was found to have x-ray evidence of infiltration of the left mid-lung zone. A patient not previously mentioned was found to have radiological evidence of spreading though symptomless pulmonary tuberculosis and another stated that two years previously he had had pneumonia. French authors, such as Hartenberg (1930), Trotot (1935), and Vidal (1942), stress the occurrence of hemiplegias during artificial pneumothorax refills, but the transient nature of these catastrophes argues a different aetiology from that in the group under review.

Summary and Conclusion

It would seem that strokes resulting in permanent hemiplegia are not such a very uncommon accident in young adult life. Although many of these patients show evidence of cardiac disease likely to give rise to emboli, the majority have no such condition. It would appear that this phenomenon may be due to either a venous thrombosis in the Rolandic system of vein or a haemorrhage, thrombosis, or embolus in the cerebral arterial system. Sepsis in the jugular vascular bed, recent pulmonary disease, and a tendency to abnormal elevation of the blood pressure are frequent associated findings.

I wish to thank Dr. Fergus R. Ferguson for help and advice in the treatment of these cases, Dr. T. S. B. Diek for the notes of the one case I did not see, and Mr. A. S. Kerr for performing the pneumo-encephalograms; also Dr. A. V. Harvey, Regional Office of the Ministry of Health, for permission to publish.

The first number of *Nutrition, Dietetics, Catering* is an attractive illustrated journal, to appear quarterly, issued by the British Dietetic Association and the Food Education Society (annual subscription 10s.: Newman Books, Ltd., 356-366, Oxford Street, London, W.1). It is intended to provide the latest news on dietetics for catering managers, canteen supervisors, and others responsible for the preparation of food, as well as medical men, and Sir Jack Drummond hopes, in a foreword, that it will contribute to banishing sodden cabbage and the other evils of bad cooking from our tables. As he points out, the standard of cooking in many of our hotels, hospitals, and institutions is deplorably low and we should be more ashamed of it than we are. Prof. Marraek draws attention to the fact that foods may have a nutritive value not apparent from the content of their various nutrients, and comments that the moral of recent investigations is that "animals, human or other, need food—not vitamins or other separate nutrients." An interesting observation made by Prof. Yudkin is that adolescence in the West African is delayed longer than is commonly believed. The psychological changes associated with puberty in girls occur at the age of about 16 or 17, and he thinks it likely that unsatisfactory nutrition is a possible cause. Mrs. Palmström, comparing Norwegian food with English, remarks that though it is similar it is often prepared differently and is eaten at different times of the day. There is no sign of war weariness in Norway. The people are strong and healthy—the women in fact probably working harder than they do in England. She points out that there are many factors contributing to this state of affairs, and wonders if the diet plays any part, in particular the relatively high consumption of meat and fish in conjunction with bread. The journal also includes news items, book reviews, and schemes for training in dietetics.

STRESS FRACTURE OF A METATARSAL IN A YOUNG CHILD

BY

LEWIS D. RUTTER, M.B., Ch.B.

Late Orthopaedic House-surgeon, Salford Royal Hospital

The following case is reported because of the early age of incidence.

Case Report

On July 23, 1946, a woman brought her child aged 4 years months to hospital, stating that until the previous day the child had been well; she then complained of pain in her right foot on walking, and it was noticed that she limped. No history of trauma was elicited. There was nothing of note in the child's previous history; walking had never troubled her before.

On examination the right foot was mildly swollen but not red, and there was tenderness along the shaft of the second metatarsal. The appearance of the left foot was normal. There was a mild genu valgum. There was no clinical evidence of systemic disease. A skiagram (Fig. 1) showed: (1) A cuff

FIG. 1.—Skiagrams taken on day of admission, showing appearance of the second metatarsal shaft.

A fine new bone formation around the mid-shaft of the second metatarsal except for a small annular area of absence of bone in contact with the cortex. It appeared as if the bone was surrounded by a ring of tissue translucent to x rays.

This appearance has been noted by Sayle Creer (personal communication) in a number of cases of stress fracture of the metatarsal, and he wonders if it masks a very small crack. (2) New subperiosteal bone formation in contact with the whole length of the metatarsal shaft except for the annular area described in (1).

In view of the patient's age a tentative diagnosis of periostitis, possibly tuberculous in origin, was made and a short leg unpadded plaster cast was applied.

On Aug. 30 the plaster was removed and the appearance of the child's foot was normal, the swelling and tenderness having disappeared. A skiagram revealed a clear fracture line across the metatarsal shaft with some separation of the fragments. The fracture showed good union. On Sept. 2, after a fortnight out of plaster, the foot appeared normal and a skiagram showed consolidation of the fracture with nothing to distinguish it from an ordinary "traumatic" fracture.

Discussion

The condition was regarded as one of stress fracture of the metatarsal on the following grounds: (1) The sudden onset of pain on walking without previous trauma. (2) Swelling of the foot (but no bruising) and tenderness of the affected metatarsal shaft. (3) X-ray appearances: the solution of continuity of the shaft and the consolidation of the fracture seen on Aug. 30, and the initial annular area of absence of bone in contact with the metatarsal shaft surrounded by a cuff of new bone. No cortical "nick" or hair-line fissure was seen: both were suggested as criteria for diagnosis by Hartley (1943), but as the skiagram on Aug. 30 showed a fracture line it is probable that the hair-line fissure was visible at some earlier stage. There is little doubt that had there been no displacement of the fragments the final skiagram would have shown complete restoration to normal architecture—said to be characteristic of "march fracture." (4) It occurred as a single lesion in the commonest bone affected by stress fracture; the other bones showed no lesion, nor was there evidence of general bone disease. (5) There was no evidence of systemic disease. No previous report of a case of stress fracture of a metatarsal occurring at such an early age was discovered in the literature. Several cases of stress fracture of the tibial shaft have been recorded in young children (Hartley, 1942); and Roberts and Vogt (1939) reported a case in a child aged 4. Stress metatarsal fractures have their maximal incidence in adolescents and young men, particularly soldiers—the incidence being so great in soldiers that the condition has been described as an occupational disease associated with military training.

My thanks are due to Mr. R. Ollerenshaw and Mr. W. Sayle Creer for their assistance and advice in the publication of this case.

Medical Memoranda

Prevention of Peritoneal Adhesions by Transplantation of Amnion

Various procedures have been suggested to prevent adhesions following repeated laparotomy. The main object is to secure normal peristalsis. Glinn, Hoehne, and other authors recommended the intraperitoneal administration of soft paraffin and similar substances; for a time camphor was employed. It was established, however, that the mixture of fats and chemical compounds was noxious. Some workers, believing adhesions to be due to the absence of fibrinolytic ferments, suggested administering Pregel's pepsin solution or "leucoferment." Mayert and Feldmann tried to prevent adhesions by air insufflation. All these procedures have been criticized.

A case is reported here in which defective peritoneum has been replaced by sterile amnion to prevent new adhesions. For this operation only those cases should be considered in which deficiencies of the peritoneum, with severe adhesions, cannot be repaired by the older procedures because they are so extensive and deep that the body itself is incapable of repair. The transplantation of amnion is intended to provide a moist gliding surface ensuring natural bowel movements. Four suitable patients have been found in the course of four years whose condition necessitated the operation.

Though the problem of adhesion formation has been clarified, there is no reliable method of prevention or treatment. It has, however, been shown that besides a sepsis, control of bleeding, and delicate manipulation of the tissues, the replacement of peritoneal defects is the most important factor in prevention. We believe that sterile amnion fulfils these requirements. Transplantation of sterile amnion in the course of gynaecological operations was performed in this country

FIG. 2.—Diagram of the second metatarsal shaft as seen in Fig. 1.

as early as 1937 by K. Burger. Only intact amnion obtained in the first stage of labour should be used for this purpose. Histological examination has shown that there is a close relation between human peritoneum and amnion. To investigate the question of how long sterile amnion can be preserved, pieces of sterile amnion were put in Ringer's solution at 2° C. and then removed severally at six-hour periods and histologically examined. No change occurred in the peritoneum or in the amnion at the end of the first six hours. Nevertheless we performed our laparotomies simultaneously with the caesarean sections in the same operating theatre; thus the amnion remained in the physiological solution only for a few minutes.

We treated four cases with amnion transplantation. The first patient attempted suicide by shooting himself in the belly. In two cases eventration due to a war injury has caused adhesions. The fourth patient had a stomach perforation followed by hernia of the abdominal wall.

CASE REPORT

He was 32 years old in 1940 when his ulcer perforated. The perforation was sutured 18 hours later. The wound separated, and secondary healing lasting many weeks occurred. One year later reconstruction of the abdominal wall was tried, but unfortunately the bowel was injured during this operation. A faecal fistula formed through which faeces were continuously passed. He suffered severe pain, and a chronic ileus developed. Two further operations were performed to relieve the ileus and to close the fistula.

He came to our ward in 1943 with a marked intestinal obstruction which could be relieved by conservative measures. He had constipation lasting for 4 to 5 days at a time and responding only to the simultaneous administration of hypertonic sodium chloride, "doryl," and "prostigmin." A pregnant woman belonging to the same blood group and having a contracted pelvis, with no other indication for caesarean section, was available. Operation was performed on the man simultaneously with the caesarean section. We removed the scar and liberated the intestinal adhesions. In the vicinity of the fistula there were a peritoneal defect measuring about 40 cm. in length and two other defects measuring 15 cm. each. These areas were covered with pieces of amnion, which were held in place by catgut stitches. Primary healing ensued, and the patient left the ward on the twelfth post-operative day. He has been followed up. He is a journeyman mason and has fully recovered.

We have operated similarly on three other patients with small peritoneal defects. They also healed by primary intention. One of them still complains at times. The patients have been followed up for 2 to 3 years. Amnion transplantation should be performed rarely, and only in cases which cannot be repaired by any other method.

Bilateral Chronic Suppurative Otitis Media with Complications

Mrs. R., aged 34, was admitted to hospital on Nov. 18, 1946, with a diagnosis of bilateral chronic suppurative otitis media complicated on the left side by: (1) Mastoiditis. Sclerotic mastoid (no swelling or oedema over mastoid). (2) Polypi, granulations, and cholesteatomata of the middle ear cavity. (3) Extradural abscess of the middle fossa. (4) Fistula of the external semicircular canal. (5) Lateral sinus thrombosis, extending down the jugular vein.

CASE HISTORY

Past History.—Known to have had attacks of bilateral otorrhoea since the age of 12. Attacks had lasted 3-6 months, with remissions of up to three months between. Not accompanied by pain or giddiness. Had measles, scarlet fever, and chicken-pox during childhood; not known whether complicated by otitis media. Scarlet fever aet. 10. "Rheumatic chill" lasting three weeks aet. 19. "Nervous breakdown" aet. 19.

Present History.—Six weeks before admission she was taken ill with giddiness and generalized headache. After 2-3 days pain in her left ear began and with it otorrhoea and giddiness on pressure over the tragus. All this subsided in a week, but during the next four weeks she did not feel too well and had attacks of giddiness. The ear continued to discharge and her head "felt queer" although there was no severe headache and no earache.

Seven days before admission she was taken ill with sudden severe pain in the ear and considerable headache and giddiness. During

the next seven days she felt hot and had repeated "shivering attacks." No vomiting. During the first week of the illness, however, she had vomited repeatedly.

On Admission.—Giddiness on pressure over tragus. Polypi and granulations removed from meatal wall and roof of attic. Lumbar puncture: Normal fluid; pressure normal; culture sterile. There were some signs of meningism but these were not very marked. High fever. Drowsy. Nystagmus, particularly on looking to right.

Put on penicillin 20,000 units three-hourly (total: 1,440,000 units) and sulphathiazole 1 g. four-hourly for three days (total: 18 g.)

X-ray Report.—Acellular type of mastoids and therefore difficult to assess degree of infection, but some infection is present in left mastoid. No cholesteatoma.

Ophthalmologist's Report.—No signs of any papilloedema. Disks normal.

By Nov. 24 she had failed to respond to treatment despite the fact that the temperature fell dramatically during the first 24 hours. Still showed signs of meningism. Lumbar puncture: Clear fluid; pressure 120 mm.; Queckenstedt test normal on both sides though sluggish—no great difference between the two sides; fluid sterile on culture and containing only 5 cells per c.mm. Blood count: W.B.C., total 19,200; polymorphs 66%, lymphocytes 25%, monocytes 9%. Smear normal.

Operation.—Nov. 25. Left radical mastoidectomy. Hard sclerotic type of mastoid. Caries found in mastoid antrum and middle ear, which was full of cholesteatomata. Extradural abscess of middle fossa and fistula of wall of external semicircular canal. Forward lateral sinus exposed and considered doubtful but not opened. Wound left open.

On Nov. 27 she still had a high swinging temperature. Mastoid reopened. Bone removed posteriorly more than half-way to occiput. Sinus found thrombosed for 1 in. (2.54 cm.) posteriorly to upper knee. Septic clot removed and sinus opened until free bleeding was obtained. Internal jugular and common facial veins ligatured in neck.

Culture of pus obtained at first operation now showed a pure growth of *Proteus*. She was therefore put on sulphathiazole 1 g. four-hourly for six days (total: 42 g.). Three days later the temperature, which was still high and swinging, fell to normal and remained down. Signs of meningism disappeared after the mastoidectomy. The nystagmus disappeared slowly after the second operation and the general condition gradually improved. The ear still discharges. She left hospital on Dec. 24, 1946, with the wound completely healed but a slight serous discharge from the meatal cavity.

DISCUSSION

Although the patient was severely ill there was no swelling or oedema over the mastoid process because she had an acellular sclerotic mastoid. In these cases the infection spreads inwards and backwards and so she developed an extradural abscess, fistula of the external semicircular canal, and lateral sinus thrombosis.

As meningitis was suspected she was put on full doses of penicillin and sulphathiazole, but these failed to arrest the progress of the disease. The mastoid was of the acellular sclerotic type, and when entrance to the antrum was effected pus gushed out and was obviously under great tension. Culture of pus showed the organism to be *Proteus*, which is penicillin-resistant.

A very anterior lateral sinus—hence more ready infection of sinus. When the sinus was opened and septic clot removed the patient made a steady but sure recovery.

CONCLUSION

Chronic otorrhoea is a common malady. When intracranial complications develop treatment with penicillin alone or in combination with the sulphonamides does not arrest the disease, and surgical intervention is necessary.

Reviews

TWO HEALTH SERVICES

Health Reform in New Zealand. By Douglas Robb. (Pp. 104. No price.) London: Whitcombe and Tombs.

The Doctor and Tomorrow. The Future of Medical Service in Australia. By Arthur E. Brown, M.B., B.Ch., F.R.A.C.S. (Pp. 136. 3s.) Sydney: F. H. Johnston Publishing Company Pty., Ltd., 34, Jamieson Street.

These two books from the Antipodes are timely and welcome because they are very relevant to the problems which our profession is facing here. Australia is proposing to nationalize medicine; New Zealand did it, more or less, over five years ago. Dr. Robb and Dr. Brown write with authority, for they both occupy prominent positions in the practice and organization of their profession. Both are firm believers in the need for a full medical service freely available to every citizen. Dr. Brown carefully examines the various ways in which Australia might do this; Dr. Robb regretfully comes to the conclusion that the New Zealand way has proved to be a very expensive failure.

The New Zealand Social Security Act of 1938 provided for everybody a free general practitioner service and part payment of hospital treatment. From the outset there was friction between the Government and the B.M.A., and there seems to be no prospect of any early agreement. Dr. Robb ascribes the effects of the scheme largely to the fact that "its impetus was political and its conception almost entirely so." Much of the friction has arisen over the amount and method of medical remuneration. There are no fewer than five ways in which the citizen can obtain medical service. (1) In a few rural areas the doctor is paid by whole-time salary. (2) If the doctor is willing to accept the method he can be paid by a capitation fee of 15s. a year with no limitation of his list. This method, though making some progress, has always been strongly opposed by the B.M.A.; in the first six months after the Act came into operation only some 50 doctors out of nearly 800 had accepted patients under this method. (3) "Fee for service." Here the patient signs a form acknowledging that he has received a service, and the doctor collects monthly from the fund 7s. 6d. for each form. Though not approved by the B.M.A. this method is being freely used. (4) "Refund" plan. The patient pays the doctor his private fee (usually 10s. 6d.), for which he is given a receipt, and with this he gets a refund of 7s. 6d. at the post office. (5) "Token" plan. Here the patient pays the doctor a token fee of 3s. and the latter collects the refund of 7s. 6d. It is not the financial side of the system which makes Dr. Robb so dissatisfied with it, for he believes the general practitioner under any of these arrangements to be better off than he was in the days of bad debts. He dislikes the "fee for service" because it "results in many trifling things being done by the doctor at 7s. 6d. a time that ought to have been done by a nurse or secretary." His fundamental complaint about the service is that it is uncoordinated and far from comprehensive. He grants that some few remote areas formerly under-doctored are now better off, but the tendency still is for doctors to gravitate to the cities. A curious factor in the constantly mounting cost of the service is the great proportion of the income of the fund that is spent on drugs and appliances. It is now 13s. 6d. a head, compared with 16s. 10d. for the general medical service. It would be interesting to know if this "free for all" supply of medicine has lessened the demand at the chemists for proprietary medicines.

Dr. Robb realizes that a country so thinly populated as New Zealand has many difficulties in providing a really full service as compared with Britain. He alludes with envy to some of the features of our new Health Service Act, but he is still hopeful that a really good service may emerge in his country. He is confident that with genuine co-operation between the Government and the profession something infinitely better than the present system could be evolved. He does not absolve the doctors from a share of the blame for the present situation: they should have shown more initiative instead of leaving the politicians to take all the credit (if any). This book is intended mainly for the New Zealand layman, and the author reminds

his readers that "the profession did not conceive or initiate the present system."

Dr. Brown's book deserves the earnest attention of all who are interested in the future of the profession, and especially of those who are concerned with the negotiations on the new National Health Service. The author is convinced that the world-wide movement towards a medical service freely available for all is one which, far from being resisted or thwarted by the profession, should be warmly welcomed. There is much information in the book about the gradual approach of Australia to this problem, but to the reviewer the most striking feature is Dr. Brown's analysis of the various methods of remunerating the profession—not because Dr. Brown is unduly concerned with finance, for he is an idealist and enthusiast, but because he believes that the success or failure of any scheme will greatly depend on the method of remuneration of the doctor. There is no other so cool, logical, and lucid an examination of the methods available known to the reviewer. The fact that the author decisively approves of payment by salary makes it all the more desirable that those who have come to a different conclusion should consider the opposing arguments, especially when they are maintained so competently and so modestly as they are here. There is no ideological nonsense about Dr. Brown. He says that he has been driven inexorably to the conclusion that only by this method can doctors be distributed "in accordance with public needs." He rules out capitation because it profits the doctor to take on more patients than he can manage and does nothing towards solving the distribution problem. As for payment per service, he rejects "any form of practice which leaves medical men and women as private traders in competition with each other."

Dr. Brown is concerned entirely with a future in which free medical service will be available to all. He does not hide his fears of a bureaucracy which fosters uniformity; he does not regard lay control as a serious danger. His main fear is of the politician, and he says, "the prospect of an inferior, badly conceived, politically devised service is a far more dangerous prospect for the public than it could ever be for the medical practitioner." Dr. Brown is to be congratulated on a courageous and lucid examination of a thorny subject. There will doubtless be many attracted, as the reviewer has been, by the logic of his advocacy who will feel that he has not given sufficient weight to the pressure which the politician will be tempted to bring to bear on a profession, no matter how or how well paid, once it has surrendered its status as a free profession.

ALFRED COX.

GENETICS

Human Genetics. By Reginald Ruggles Gates. Volumes I and II. (Pp. 1518; illustrated. £5 for the two volumes.) New York: The Macmillan Company. 1946.

Probably no one except Prof. Gates could have written this book, but, fine though the result is in some ways, we wonder whether anyone, even Prof. Gates, should ever have made the attempt. He covers the whole field chapter by chapter, and there can be few human inherited abnormalities, as well as many other inherited differences, that he does not describe. His knowledge is encyclopaedic and the 5,500 references successfully guide the reader to the key papers and books on each subject. There is an admirable index of 90 pages with full cross-references. It is the text that raises the suggestion whether the author has been too ambitious.

When Prof. Gates is discussing subjects especially familiar to him, and to which he himself has contributed, he presents us with a lucid, balanced, and well-digested summary. The chapter on the blood groups, for example, is excellent. When he was writing the book our knowledge of the rhesus factor had not attained its present clarity, but he explicitly recognized that a successful synthesis was imminent and few outside the ranks of the professional serologists could have achieved so much. One man, however, can have only a second-hand acquaintance with most of this vast subject and its scattered literature, and in many chapters the sureness of touch seen in that on the blood groups is lacking. The running commentary is often a complex and exhausting mixture of the historical, the pathological, the clinical, the genetical, the purely descriptive and the statistical. Some out-of-date opinions seem to have been included from

the previous version of 1929. Sometimes erroneous or fantastic speculations are given the same emphasis as thorough and competent researches and surveys. For example, the account of spina bifida starts with a consideration of experimental work on the frog, followed by a reference to its anatomical features. The author then refers to an instance of three cases in one sibship and a theory of the relationship of the occult to the manifest condition. After that he digresses to its possible relation to the erect posture, with a remark on sex limitation. Next he discusses a study of its relation to nocturnal enuresis, the author of which considered this latter condition to be a simple recessive. Finally he mentions some other deformities with which spina bifida may be associated, and interpolates a paragraph on its frequency in the population. The inquirer who wishes to know whether spina bifida is inherited and, if so, how will not be much wiser, though his attention is directed to useful references from which he may find the answer for himself. In the chapter on the inheritance of normal mental differences, after a few brief references, Prof. Gates starts with an account of Hurst's hypothesis of six factor pairs, but does not point out that a scheme involving six factor pairs would fit almost anything and would be difficult enough to establish even with many thousands of observations on a self-fertilized plant.

One opinion should not be allowed to pass without challenge. On p. 213, in dealing with the usual recessive form of retinitis pigmentosa, Prof. Gates says: "Obviously those transmitting this very serious defect should not have children." If he means that a couple who have had an affected child have a one-in-four chance that any further child will also be affected and would therefore be wise to refrain from having more, many will agree with him, but presumably he means that an affected person or a known carrier should not have children; yet for every such person at least 100 others, quite unsuspected, are carrying and transmitting the gene. The eugenic effect of such abstinence is negligible and there is a far stronger case for the opposite opinion: that a sufferer from a rare recessive defect or a known carrier should not be deterred from parenthood provided he does not marry a blood relative and—as will nearly always be the case—so long as no affected child appears.

In some places this book is clear and authoritative, in others obscure, and in a few misleading. It is unsuitable for the student, but the expert will value it highly.

J. A. FRASER ROBERTS.

EXAMINING THE EYE

Clinical Methods of Neuro-Ophthalmologic Examination. By Alfred Kestenbaum, M.D. (Pp. 384. \$6.75.) New York: Grune and Stratton. 1946.

This well-produced book, an important and welcome addition to the rather limited literature on the subject, contains a large amount of clearly presented and accurately classified information not generally available in textbooks. The author considers clinical entities only incidentally; he concentrates on methods of examination and on the interpretation of findings. An introductory chapter on the optic pathway is followed by one on the field of vision, in which he discusses in detail both methods and field defects. Three successive chapters deal with physical signs in lesions of the optic nerve, chiasma, and retrochiasmal pathways respectively. A further three chapters are devoted to eye muscle palsy, gaze movement, and nystagmus. He gives an account of the different modes of disturbance in symmetrical eye movement in the succeeding chapter, and then discusses abnormalities in the reaction of the pupil; in the concluding three chapters he deals with miscellaneous physical signs, palpebral fissure, and functional disturbances, giving a general survey of the routine neuro-ophthalmological examination.

The text is not easy reading, but this is not the author's fault. His subject has received less attention in the past than it merits; in consequence there is much here that is unfamiliar, though it ought to be widely known. The logical division and subdivision of the text should help the reader considerably, though it is unfortunate that it contains many unusual abbreviations. The book should do much to further the systematic study of ophthalmic neurology.

ARNOLD SORSBY.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Vitamins and Hormones. Ed. by Robert S. Harris and Kenneth V. Thimann. Vol. IV. (Pp. 406. \$6.80.) New York: Academic Press. 1946.

Papers on recent advances of vitamin and hormone investigations.

The Intelligent Use of the Microscope. By C. W. Olliver, A.M.I.E.E., F.R.M.S. (Pp. 182. 12s. 6d.) London: Chapman and Hall. 1947.

Describes how to get the best out of a microscope and includes a chapter on photomicrography; for the student.

La Silicosis Pulmonar. By Dr. Hugo Dooner. (Pp. 195. No price.) Santiago, Chile: Zig-Zag, S.A. 1944.

An account of silicosis with a historical introduction, skiagraphs, and bibliography.

Preventive Medicine and Public Health. By Wilson G. Smillic, A.B., M.D., D.P.H. (Pp. 607. 30s.) New York: The Macmillan Company. 1947.

The technique of hygiene and public health for the medical practitioner and student.

Tuberculosis Reference Statistical Yearbook. By the New York Tuberculosis and Health Association. (No price.) New York. 1946.

A summary with tables of tuberculosis morbidity and mortality in New York with comparative figures from the United States and other countries.

The Louse. By Patrick A. Buxton, F.R.S. 2nd ed. (Pp. 164. 10s. 6d.) London: Edward Arnold. 1947.

An account of the lice that infest man, their medical significance and control.

Medical Services by Government, Local, State, and Federal. By Bernhard J. Stern, Ph.D. (Pp. 208. 8s. 6d.) New York: The Commonwealth Fund (London: Geoffrey Cumberlege). 1946.

A monograph on the Government Medical Services of the United States.

Una Epidemia de Peste Bubonica en el Siglo XVI. By Dr. Don Jose Viñes Ibarrola. (Pp. 133. No price.) Pamplona: Editorial Aramburu. 1947.

An account of a plague epidemic in Spain in the 16th century, with reference to original sources.

The Glean. By Warren Chetham Strode. (Pp. 90. 6s.) London: Sampson Low, Marston and Co. 1947.

A National Health Service drama which was reviewed on Dec. 14, 1946 (p. 914).

The Microscope. By Theodore Stephanides, M.D. (Pp. 160. 10s. 6d.) London: Faber and Faber. 1947.

An account of the microscope and its use; for students.

La Désinsertion Extra-plénrale des Symphyses Pulmonaires sous Contrôle de la Pleuroscopie. By Dr. Jean Brailion. (Pp. 120. 210 francs.) Paris: Librairie Maloine. 1947.

An account of Michetti's operation for pleural adhesions in collapse therapy.

The Personality of Man. By G. N. M. Tyrrell. (Pp. 295. 1s.) Harmondsworth, Middx.: Penguin Books. 1946.

Discusses paranormal phenomena, including telepathy, and their significance to man.

Massage and Remedial Exercises in Medical and Surgical Conditions. By Noel M. Tidy, M.C.S.P. 7th ed. (Pp. 480. 25s.) Bristol: John Wright. London: Simpkin Marshall. 1947.

This edition includes a short description of carbachol ionization.

Medical Diseases in Tropical and Sub-Tropical Areas. By the War Office. 8th ed. (Pp. 396. 7s. 6d.) London: His Majesty's Stationery Office. 1946.

This edition includes new articles on infective hepatitis, leprosy, nutritional diseases, tropical eosinophilia, and D.D.T. Many other sections have been rewritten.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 12 1947

A CENTURY OF CHEMISTRY

The antiquity of medicine as an art should not obscure the fact that the origin of medicine as a science dates chiefly from the development of chemistry. An important stage in that development will be celebrated in London on July 15-17: the foundation on Feb. 23, 1841, of the Chemical Society, the first organization in the world to make the study of chemical science its specific province. The centenary celebrations were postponed from their original date on account of the war, as also was the Eleventh Congress of Pure and Applied Chemistry, which it had been planned from the beginning should be held in London, as a compliment to the Society. The medical man may see some compensation in the delay, for in the interval his debt to the chemist has become even more evident. Environmental medicine has benefited, in temperate as well as in tropical conditions, from the new insecticides. Blood storage, with its background of chemical experiment and preservatives, has given a new flexibility to emergency surgery; and penicillin, to which the chemist also contributed, has increased confidence in the result. The physician, confronted for the first time in modern medicine with the prospect of widespread malaria and empty quinine bottles, found his position in the end to be stronger and not weaker as a result of the chemist's work.

To concentrate on recent events such as these would nevertheless be to miss the real nature of the chemist's contribution; for these advances, however important in themselves, have been on the surface, whereas the whole structure of physiology has depended on the insight which chemistry alone could provide. Without recognition of the individual nature of different gases, and the power to make their properties the subject of experiment, we could not have understood the function of breathing. Without knowledge of combustion, physiological meaning could not have been attached to the circulation of the blood, nor could even the crudest approach to nutrition have been made. From these necessary beginnings succeeding discoveries have branched out ever more widely; and, as the President of the Royal Society has pointed out,¹ chemistry has benefited in turn from the reciprocal stimulus which biological studies provided. A classic example was the synthesis of urea by Wöhler in 1828, and it may be worth emphasizing that this was only thirteen years before the foundation of the Society. Wöhler's work represented rather the removal of a barrier than the beginning of synthesis in the ordered and modern sense, but, as has since been stated, it provided "a charter of liberty for organic chemists."

Synthetic chemistry proper is generally dated from the work of Berthelot in France, about 1853, on glycerides and fats. The chance discovery of synthetic mauve by Perkins (later President of the Society) in 1856 may seem, however, to have exercised a greater immediate influence on the course of medicine. Apart from its distressing effect on Victorian taste and the obvious stimulus which it gave to the development of a dyestuffs industry it may be said to have paved the way for the introduction of staining techniques in cytology and bacteriology and thus to have provided the technical means for the development of two branches of medical science. Add to this the importance of the methylene blue test in the examination of milk, the many colour indicators now taken for granted, and the development of modern chemotherapy from the partly mistaken doctrine of dyestuff absorption, and some measure of medicine's debt to Perkins's discovery is obtained. To the same period, although obviously unconnected with Perkins's work, belongs the synthesis of the first salicylate. Finally, as one example of an incidental discovery, we may recall that the first use of anaesthetics in surgery falls also within the period covered by the Chemical Society's history.

Contemporary interconnexions between medicine and chemistry are most conveniently illustrated from the Congress programme. Out of the fourteen sections three of particular interest are devoted to biochemistry, food and nutrition, and chemistry in relation to medicine and therapeutics. The biochemists will meet under the presidency of Prof. Tiselius, of Uppsala. He has made many contributions to both protein and carbohydrate chemistry, and both these divisions are well represented, as also is the now rapidly growing chemistry of enzymes. Further subjects include the preparation of purified antibodies, Stacey's work on bacterial polysaccharides, and the nature of the combination of bacterial enzymes with their substrates. All these are investigations of probable importance, and the same may be said also of the first attempt by Francis and Wormald to apply radio-active tracers to the study of immunological reactions. A useful joint symposium on nutrition has been arranged with the section of applied zoology. Recent experience has shown that farm animals, owing to the greater localization of their natural diet, afford opportunities not easily found in human beings for the study of both trace mineral elements and mineral antagonisms. Another recent development has been the recognition that knowledge of calorie requirements, and particularly of physiological adaptation to a low calorie intake, is still incomplete. It is common knowledge among nutritionists that work in the occupied countries of Europe has led to a number of fundamental advances; but, so far as the present Congress is concerned, we must be content with information from France, Belgium, Bengal, and the Far East, and with learning the lessons to be drawn from the Minnesota rehabilitation experiment.

In the medical section chemotherapy occupies, inevitably, the place of honour. Sir Howard Florey will give a general introduction, and Waksman will follow with an account of streptomycin. Shannon's summary of anti-malarial research in the United States may be expected to add something to existing knowledge, particular interest

¹ Robinson, Sir R., *British Medical Journal*, 1946, 1, 943.

attaching to those investigations aimed at producing a less toxic substitute for pamaquin. Papers on the natural formation of thyroxine and on the synthetic oestrogens remind us of the chemist's contributions to endocrinology. On the other hand, chemical carcinogenesis, together with the newer experimental methods used in its study, is perhaps less fully represented than might have been expected. Finally, there is a symposium on industrial toxicology, on which also there have been recent advances in knowledge.

One effect of the centenary celebrations and of the Congress should be to bring home to the medical man a more lively appreciation of the close relation between the two disciplines. In chemistry and physics research has been notably assisted by a comparatively small number of laboratory workers who have so far become biologists as to obtain a real insight into the structure and functions of the living material which they have chiefly investigated. There is no less need, as we have pointed out on another occasion,² for medical men themselves to gain some understanding of the chemist's methods and limitations. It is not enough to learn, usually under duress, the names of the principal chemical elements and radicals or the rudiments of systematic analysis, for these accomplishments as such imply no more than that the medical man is an inferior chemist. It is more important for his proper contribution to the partnership that he should understand how chemists think, and, in particular, the ideas and methods which they use in working out structural constitution. In addition it is desirable that he should know something of the powers and limitations of the newer chemical techniques, including, for example, chromatography,³ micro-analysis,⁴ and the research uses of radio-isotopes.⁵⁻⁷ He need not himself be a chemist, but he should know enough to understand the sort of questions that may usefully be asked.

FAT ABSORPTION AND METABOLISM

The intervention of seven years of war has broken many of the threads of international co-operation in research, so that accumulated data, new techniques, and fresh conceptions now await integration. As the pattern of post-war developments in research becomes clearer it is apparent that the problem of fat absorption and metabolism has been and is being energetically studied in both the laboratory and the clinical fields in many countries. The striking advances in our knowledge of fat metabolism during the last decade have accentuated the need for an adequate understanding of the mechanism of intestinal absorption of fat.⁸ The lipolytic hypothesis of fat absorption,⁹ which was generally accepted ten years ago, does not adequately explain many subsequent observations,¹⁰ nor has it formed a satisfactory basis for the investigation of defective fat absorption in human subjects. The problem must be re-

examined in every detail. If the fundamental mechanism of fat absorption can be elucidated in experimental animal and human subjects, it may be possible not only to correlate the absorption and metabolism of fat but also to gain a clearer conception of the process of absorption in general. A more detailed approach to these problems, tracing each step in the passage of fat from the lumen of the intestine to its ultimate destination in the body, combined with the application of new techniques, should soon clarify our views.

Study of the clinical aspects of fat absorption was intensified during the war because of the high incidence of tropical sprue among British troops overseas¹¹ and non-tropical sprue among the civilian population in Britain and these cases were an invaluable means of studying the fat absorption mechanism in human subjects. It is essential, however, that investigations should be carried out on a quantitative basis¹² and that further methods should be devised for the more detailed study of aetiological factors. Best and his colleagues¹³ at Toronto opened up a new field of investigation in fat metabolism by demonstrating the lipotropic action of choline. Subsequently other substances affecting the deposition and mobilization of fat from cells have been described. Further experimental studies are required to establish the relationships between these substances and to elucidate their mode of action and their role in normal metabolism. The observations so far made in clinical medicine have given anomalous results. There does not seem to be sufficient information at present on the action and effects of lipotropes in human subjects.

The study of adipose tissue remains largely neglected although Schoenheimer and his collaborators¹⁴ have introduced a new conception of its dynamic nature. Little is known of the mechanism of fat deposition or its removal from the depots. While cases of obesity have been studied and the application of Newburgh's views¹⁵ has been attended by success in many cases, it is unlikely that clinical problems involving the metabolism and deposition of fat will be solved until the fundamental physiological facts about adipose tissue have been determined. Contributions have been made to many other aspects of fat metabolism. Progress has been achieved in the study of fat oxidation, and a revision of ideas on the relationships of carbohydrate and fat metabolism is leading to a more rational view of ketogenesis. Some years ago Burr and his colleagues¹⁶ demonstrated the importance of certain fatty acids in the diet in animals. The application of these findings to human subjects has been somewhat disappointing, but, again, therapeutic trials have been carried out without any clear conception of the physiological significance of these essential fatty acids in man.

Animal proteins are usually associated with lipoids, and in many instances this association is fundamental to the normal biological activity of the protein material. The nature of these associations and the factors concerned in their stability are largely unknown. Work is in progress in several laboratories, using modern chemical and physical

techniques, to determine the essential data. Since lipoprotein association is concerned in fat transport, membrane structure, blood coagulation, nerve structure, immunological reactions, and probably fatty degenerative changes, the importance of investigations in this field to physiology, pathology, and clinical medicine is likely to be considerable. The absorption and metabolism of fat presents a fascinating research field. It requires the co-operation of chemists, physicists, physiologists, and clinicians. As new facts come to light it is hoped that an adequate physiological basis will be established in human subjects as well as in experimental animals before attempts are made to apply the facts therapeutically, for it is only by building on a sound foundation of proved experimental data that successful clinical application can be achieved.

INTERNATIONAL MICROBIOLOGY

The fourth International Congress of Microbiology, which before the war was triennial, is to be held in Copenhagen at the end of this month. The Permanent International Commission for the organization of these congresses has been reconstituted and will also meet in Copenhagen to consider the future policy of the International Association of Microbiologists in relation to other scientific bodies. This Permanent Commission consists of representatives of twenty-eight countries. The British representative is Sir Alexander Fleming; the United States is represented by Dr. Stuart Mudd, of the University of Pennsylvania; Denmark by Prof. Th. Madsen; Belgium by Prof. Jules Bordet; Canada by Prof. E. G. D. Murray, of McGill; Eire by Prof. J. W. Bigger, of Trinity College, Dublin; and India by Sir S. S. Sokhey, director of the Haffkine Institute, Bombay. The question for decision will be whether the International Association should ally itself with the International Union of Biological Sciences, forming a section within that body, or should become a separate union in the International Council of Scientific Unions. Through either of these organizations it would be linked with Unesco, and both courses have their advantages. A decision either way would mean only a formal change of status and no surrender of independence. If it is decided to become a section within the International Union of Biological Sciences the advantage would be in the organic connexion of microbiology with other aspects of biology—botany, zoology, genetics, and experimental cytology, and so all these sciences would be under one international umbrella. Apparently the International Union would also publish the reports of the international congresses of its sections with the help of Unesco. On the other hand, there are such strong links between microbiology and the medical sciences that some may think there should be a separate union within the International Council for Scientific Unions. The British and American representatives favour the first of these alternatives.

One of the reasons for the re-establishment of international microbiology is the need for restoring the various collections of type cultures throughout the world and for preparing a world catalogue of the available strains. A new central collection of type cultures has lately been organized at Lausanne under the direction of Prof. Paul Hauduroy, and proposals will come forward at Copenhagen for the association of this centre with the others. Dr. Joseph Needham, head of the Division of Natural Sciences of Unesco, has stated the interest which his organization takes in the furtherance of international scientific unions.

Such unions will serve three primary purposes—as machinery for the exchange of information, as organizers of international congresses, and as channels for the funds which Unesco may provide for international scientific undertakings.

ETHER IMPURITIES

From the earliest days of anaesthesia the importance of using chemically pure and unadulterated ether has been stressed. The demand for pure ether has not appreciably altered through a century of anaesthesia, and to-day the pharmacopoeias of almost every country lay down stringent chemical and physical criteria for ether which is to be used for anaesthetic purposes. These precautions, however, by obviating impurities which derive from the process of manufacture, do no more than ensure pure ether in the unopened bottles as supplied by the manufacturers. There are other impurities, of which the most important is ether peroxide, that make their appearance as a result of autoxidation during storage. There is still some doubt as to how important these impurities are. From the physical point of view it seems that the presence of ether peroxide renders spontaneous explosion possible. But their effect on the human organism is less certain. In the literature of ether anaesthesia, anaesthetists have repeatedly made them the scapegoat for any complication or mishap which they could not explain without implicating their own human fallibility. Sudden death on the table, post-operative pulmonary complications, vomiting, convulsions, and every sort of difficulty during induction and maintenance of anaesthesia have all been attributed to impurities. In fact, there has been enough feeling on the matter, even without much scientific evidence, to make manufacturers and pharmacists use considerable effort to ensure that ether for anaesthesia is supplied as pure as possible.

In the extensive literature on ether impurities the monograph of Reimers,¹ dealing with the chemical aspect, stands out as a most important contribution. Lindgren² now carries Reimers's work a stage further by investigating not only the factors which enhance autoxidation but the biological and clinical effects of using autoxidized ether for anaesthesia. He found that autoxidation is dependent on such factors as the ether storage temperature and the nature and thickness of the glass in which the ether is kept. Lindgren also determined the effectiveness of various inhibitors of autoxidation, particularly diphenylamine. Ether to which such a stabilizer is added shows no appreciable oxidation over long periods of time. Biological tests revealed a close relationship between induction time and peroxide content; the greater the peroxide content the weaker the ether as an anaesthetic and the longer the induction time.

Of even greater interest are the results of clinical tests which Lindgren carried out on over two thousand patients. A clinical comparison with statistical tests was made between samples of pure anaesthetic ether complying with pharmacopoeial standards, autoxidized ether, and ether stabilized by the addition of diphenylamine but kept under conditions which would normally result in much autoxidation. Observations on the ether consumption, induction time, excitement and vomiting during induction, circulatory disturbances, convulsions, and post-operative pulmonary complications were carefully made. In summing up, Lindgren states that there was no significant difference in the actual course of the anaesthesia or in the frequency of post-operative pulmonary complications between the samples of ether used.

¹ *Acta til Narkose*, 1943, Munksgaards, Copenhagen.
² *Acta chir. scand.*, Suppl., 110, 1946.

The work of Reimers and of Lindgren is of importance when, as in the recent war, large stocks of ether are accumulated and the problem of their disposal arises. It is probable that much needless waste of such stocks took place, on the ground that possible autoxidation constituted a hazard to patients. The use of autoxidized ether is nevertheless undesirable, and the question of preventing this process must be seriously considered by ether manufacturers in this country. When a pure ether supply to the patient is ensured the real or imaginary bogey of ether impurities as a cause of bad anaesthesia may at last be laid.

SPINAL PUMPING

The iron curtain which has become so familiar to the political student of Europe is an effective barrier to the spread of scientific ideas. Behind it, untouched by what we consider the main stream of contemporary medical thought, the Soviet system of medicine has been growing up; the occasional glimpses vouchsafed to us have done little but confirm the belief that it is developing along lines different from ours. Often these glimpses have revealed views which we have been unable to accept and notions which would not fit into the framework of our methodology. Such reasons give an added interest to any paper concerning itself with Soviet medical thought or practice and ensure that a recent publication by Gillman and Gillman,¹ of Johannesburg, will be read with careful attention. These authors report their experiences with Speransky's method of "spinal pumping" in the treatment of rheumatic fever and rheumatoid arthritis.

Speransky, a pupil of Pavlov, believes that the nervous system plays an important part in the genesis of acute and subacute arthritis. The reasons for his belief and the steps that led him to adopt this bizarre method of treatment remain buried in the Russian tongue. To carry out his method a thin lumbar puncture needle is introduced with the patient lying on one side; a 10 ml. syringe is attached to it when cerebrospinal fluid is flowing freely. The process of "spinal pumping" consists of withdrawing 10 ml. of fluid and re-injecting it into the theca; this is repeated about twenty times; it is usually followed by considerable autonomic disturbance, particularly sweating and cutaneous vasodilatation. Seventy cases were treated; 42 of 48 patients with acute or subacute arthritis were distinctly improved—38 indeed recovered completely; 12 of 22 chronic cases were improved. The results are of great interest, and it is to be hoped that others will give this method a trial. Nevertheless the Gillmans' paper is not wholly satisfying. We are told that from "a series of brilliant experiments" Speransky concluded that the nervous system played a major part in the pathogenesis of inflammatory processes, but we are not told what drove him to devise the procedure of "spinal pumping." Our ignorance of these steps does not indicate that the method is without a logical basis, but without this knowledge it is unlikely to appeal to the British physician until its efficacy is established.

GLUTAMIC ACID

Glutamic acid is an important constituent of brain tissue. It is the only amino-acid known to be metabolized by the brain, in which it increases oxygen consumption. Wheat gluten contains glutamic acid in abundance. The connexion between our daily bread and the functioning of the brain has recently been brought into the foreground of speculation by Mellanby's experiments with dogs.² Feed-

ing dogs of the same litter at one time on untreated flour and at another time on flour commercially bleached at "improved" by nitrogen trichloride, he found that dogs fed on the improved flour developed canine hysteria, from which they remained free while on a diet of untreated flour. It is at least possible that it was the glutamic acid of the flour gluten which had been chemically altered and made toxic.

In the United States interest in these questions was first focused on the feeding of glutamic acid to rats, from which it was found that their powers of maze learning were improved. Zimmerman, Burgemeister, and Putnam³ have now reported an experiment in which glutamic acid was fed to nine children of whom seven were epileptic and two mentally retarded. Their ages ranged from 16 months to 17 years. Sufficient glutamic acid was given to produce noticeable increase in motor activity, the dose varying from 6 to 24 grammes a day by mouth; this dosage was maintained for six months. The children were investigated before and at the end of this period by intelligence tests. In every one of the epileptic children there was clinical improvement, five of the seven ceasing to have fits; but treatment by phenobarbitone and other drugs had been continued, and the improvement cannot be attributed with any certainty to the glutamic acid. Apart from the two youngest children, aged 16 months and 2 years, both of whom were seriously retarded, all the remaining children showed a greater improvement in intelligence than could be expected from lapse of time alone. There were improvements in the intelligence quotient of from 5 to 13 points with an average of 9. The question arises whether the improvements could be accounted for by the great reduction in the severity of the epileptic fits. After discussing the literature and the results in a control group of epileptic children under treatment but not with glutamic acid the authors conclude that their findings cannot be explained in this way. They also believe that the practice effect of testing is negligible in their experimental group. Though the smallness of the experimental group imposes caution they conclude that glutamic acid may have a genuine facilitating effect on mental functioning in human subjects as it does in rats.

It is perhaps permissible to speculate whether the improvements in intelligence were due not to a direct action of the extra glutamic acid but to its protective action against the subclinical ill-effects of the children's normal diet of bread made from treated flour.

COAGULATION TIME AND ANTIBIOTICS

Apart from allergic manifestations there have been few records of any serious reactions resulting from the repeated administration of penicillin. There is, however, considerable evidence to show that both penicillin and streptomycin may produce changes in the coagulation time of the blood. In 1943 Moldavsky, Hasselbrook, and Cateno⁴ found that in patients under treatment with penicillin the clotting time was materially shortened after an injection. These observations have been confirmed by Macht and Ostro,⁵ who observed also that when injections of penicillin were given to two patients suffering from haemophilia no shortening of the coagulation time resulted.

The specimens of penicillin on which the original observations were made were probably impure. The whole question has therefore been investigated again by Macht. With amorphous penicillin of a dozen or more brands

⁴ *Science*, 1945, 102, 36.

⁵ *Ibid.*, 1946, 103, 402.

⁶ *Ibid.*, 1947, 105, 313.

marked acceleration of clotting time was found both in man and in animals. The increase in the time of clotting as usually noted within fifteen to twenty minutes of the injection but was often most pronounced about one hour later; the effect persisted for several hours in every case. The route of administration appeared to make little difference; the reduction in clotting time was noted after intravenous or intramuscular injection and when the penicillin was given by stomach tube. With a highly purified sodium salt, consisting almost entirely of penicillin G, the thrombotic effect was much less striking. Relatively pure specimens of the four penicillins were then studied. Penicillin X (hydroxybenzyl penicillin) was found to be the most active in reducing the coagulation time; then came K (n-propyl penicillin), F (pentyl penicillin), and G (benzyl penicillin). A curious finding was that the addition of a small dose of penicillin X to penicillin G apparently had a synergistic effect, producing an increase in coagulation time greater than that following a much larger dose of penicillin G alone. Streptomycin, too, has the effect of increasing the coagulation time of the blood in cats and rabbits. Rabbits which had received a number of injections of penicillin the coagulation time of the blood remained shortened for a considerable period, so that fresh experimental animals had to be employed. Both in rabbits and in cats the thromboplastic action of penicillin can be overcome by suitable doses of dicoumarol.

Since nature has provided generous checks and balances in the higher animals, as well as compensatory and reserve faculties, the danger of thrombosis in clinical practice is probably small. Nevertheless such cases are already being recorded. Frada⁷ described in four patients embolic accidents which he attributed—in the light of recent findings—probably correctly—to the action of penicillin in increasing the coagulability of the blood.

CRIMINAL LAW IN THE NEW ORDER

As society evolves, the law is one of the last institutions to change. Criminal law changes even more slowly than the other branches. This fact is likely to prove extremely important in the near future, and unless conscious and successful efforts are made to bring our criminal law into line with present-day fact and sentiment the existing disrepute for all law, already dangerous, may increase to a disastrous extent. The treatment of the criminal has received a good deal of attention during the last fifty years; the criminal law itself has hardly been touched. As set out in his recent book,⁸ Dr. Mannheim's thesis—and it seems self-evident—is that before we begin to consider how convicted law-breakers should be treated an analysis should be made of those actions of which a prison sentence or a probation order may be the legal consequence. In criminal law, unless it is to lose its meaning, must reflect more or less faithfully the fundamental values on which contemporary society rests. Dr. Mannheim's idea is therefore to consider the repercussions on the criminal law which have been produced by the present crisis in values, and the practical consequences which must flow from them. He points out that in any attempt to reconstruct criminal law two basic problems must be faced: those of defining the most important values of the present world, and of deciding whether those values should be protected by the criminal law or by some other agency. This investigation has led him over a very wide field and into a number of paths which at first sight seem to have little connexion with criminal law. His first section, on the

protection of human life, considers first the individualistic aspect, under the headings of homicide, suicide, and euthanasia; and then the collective aspect, including birth control, abortion, and the extermination of the socially useless or restriction of their reproduction. Under the protection of sexual and family life he ranges over the field of sexual offences and offences against the family. He then deals with the even larger subject of economic crime, which has undergone much more rapid change than has crime against persons. He criticizes the traditional approach to the protection of property and sketches what he considers the necessary new approach. In his study of offences against property (usury, profiteering, fraud against the revenue, monopoly), and of protection of and against labour (strikes and absenteeism), he is even less conventional. Having surveyed present values, he makes a series of recommendations which have already found wide support but of the fulfilment of which there is at present no prospect: they include the abolition of punishment for suicide, the legalization of euthanasia, the introduction of degrees in murder, the legalization (within limits) of sterilization and abortion, and many other controversial suggestions.

In the second half of his book Dr. Mannheim draws up a blueprint for the criminal justice of the future, with a view to making it more scientific and more democratic, and to introducing more international co-operation and more planning. Briefly, he advocates a more modern type of legal draftsmanship; greater facilities for permanent observation of the working, and frequent improvement in the wording, of law; and better integration of the work of experts in criminal cases. He would have a "treatment tribunal" to advise the courts before a prison sentence is passed; he would prohibit short sentences and extend the scope of the indeterminate sentence. He would set up summary courts with a stipendiary chairman and lay assessors; he would abolish trial by jury except in political cases. Naturally, he advocates the extension of legal aid for defendants. He wrote before the publication of the Rushcliffe report but broadly agrees with its findings. He calls for a comprehensive planning programme to co-ordinate all the interested agencies, public and private. This is a profoundly interesting and imaginative piece of social research by a highly experienced and qualified expert, and deserves a prominent place in the attention of reformers.

HONORARY PHYSICIANS TO THE KING

The following have been appointed Honorary Physicians to the King for a period of three years: Dr. James Boyd, F.R.C.P.I., Chief Medical Officer, Ministry of Health and Local Government and Ministry of Labour, Northern Ireland; Sir William Allen Daley, M.D., F.R.C.P., Medical Officer of Health and School Medical Officer, London County Council; Dr. Alexander Mackenzie Fraser, Medical Officer of Health of the Burgh and County of Inverness (Highlands and Islands Medical Service); Sir Walter Haward, O.B.E., M.B., B.S., Director-General of Medical Services, Ministry of Pensions; Sir William Wilson Jameson, K.C.B., M.D., F.R.C.P., F.R.C.O.G., Chief Medical Officer, Ministry of Health and Ministry of Education; and Dr. Norman Tattersall, Principal Medical Officer, Welsh National Memorial Association, Cathays Park, Cardiff. The following have now completed their term of office as Honorary Physicians to the King: Dr. J. A. Charles, F.R.C.P., Sir Andrew Davidson, M.D. Glas., F.R.C.P.Ed., Dr. H. M. C. Macaulay, Dr. E. R. A. Merewether, F.R.C.P., Dr. W. Rees Thomas, F.R.C.P., and Prof. G. S. Wilson, F.R.C.P.

A.M.A. CENTENARY EXHIBITS AND PAPERS

A general account of the Centenary Meeting of the A.M.A. has already been given in leading articles in the *Journal* of June 7 and 28, and in the former issue appeared an article on the history of the A.M.A. by Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*. We print below a summary of the proceedings of the meeting. In the space available it is possible to refer to only a few of the many interesting exhibits and papers. Eighteen different sections were holding simultaneous meetings; the House of Delegates was conducting its business at the same time; and on top of this there were the superb scientific exhibits to visit.

Scientific Exhibits

The scientific exhibits were assembled under the general direction of Dr. Thomas G. Hull in the Convention Hall in Atlantic City—the largest hall for this purpose in the U.S.A. The general layout of the exhibits was similar to that of some of those housed in the Wellcome Museum. Each consisted of a booth whose back and side walls were used for the exhibition of charts, diagrams, maps, x-ray films, photographs, mounted specimens, and anatomical models. Pamphlets describing the work of the exhibits were obtainable, and the exhibitors themselves were on duty most of the day to demonstrate and discuss the work shown.

The majority of the exhibits were competitive. A gold and a silver medal and other awards were given for two classes of entry. Drs. George E. Burch and Paul Reaser, of the Tulane Medical School, New Orleans, won the gold medal for original work with their exhibit entitled "Radio Elements and Mechanism of Congestive Heart Failure: Radiosodium (Na^{24} and Na^{22}). This work showed that in patients with congestive heart failure "there was a much more prolonged retention of sodium than in the normal subject." The awards in the second group were for exhibits which "do not exemplify purely experimental studies but are judged on the basis of excellence of correlating facts and in their presentation." The gold medal in this case went to Drs. George F. Cahill and Meyer M. Melicow, of the Squier Urological Clinic, Presbyterian Hospital, New York, for the exhibit on tumours of the adrenal gland.

In addition to entries falling into these two groups the committee sponsored four special exhibits: on cardiovascular diseases, fractures, fresh pathological material, and physical medicine. The cardiovascular exhibit under the guidance of Paul Dudley White, of Boston, covered an amazingly wide range, and included a fine selection of historical works on the heart and the circulation. Under the chairmanship of Kellogg Speed, of Chicago, the fracture exhibit was accompanied by continuous demonstrations throughout the week; in order to make this possible no fewer than thirty orthopaedic surgeons assisted the committee.

A group of workers from the University of Minnesota presented an interesting exhibit on the physiological problems of bulbar poliomyelitis. The epidemic of last year, the largest since 1916, attacked 25,191 persons throughout the U.S.A. There were 2,875 cases in Minnesota alone, and the exhibit was based on the experience obtained in treating 183 patients suffering from bulbar poliomyelitis, classified by the Minnesota group thus: (1) *Cranial Nerve Nuclei Type*, with the symptom of difficulty in swallowing. (2) *Respiratory Centre Type*, with deficient oxygenation of the blood. (3) *Circulatory Centre Type*, with changes in pulse rate, rapid fall of blood pressure, and the general symptoms of shock. (4) *Encephalitic Type*. "Many patients with involvement of the bulb of the brain show signs of confusion, apprehension, and anxiety. These symptoms are chiefly due to the lack of oxygen in the brain. Only rarely is there actually virus infection of the cortex of the brain producing these typical encephalitic symptoms." (5) *Bulbar-cervical Spinal Type*. Patients have a mixture of the above symptoms and also may show paralysis of the muscles of respiration. Treatment includes nasal tube feeding, tracheotomy, and oxygen therapy. The exhibit included the oximeter—an electronic device which, clipped on the patient's

ear, immediately records the amount of oxygen circulating the blood stream.

Another exhibit on poliomyelitis was presented by the National Foundation for Infantile Paralysis. With modern methods of treatment, it was stated, approximately 50% of cases of poliomyelitis recover completely; approximately 20% suffer severe and another 20% mild paralysis; the mortality rate is 5-10%. According to maps showing the distribution of poliomyelitis throughout the world, the first sizable European epidemic appeared in Norway and Sweden in 1905; the first sizable epidemic in the U.S.A. occurred in New York City in 1907. Severe epidemics did not arise in Japan until 1938 and 1940.

Before leaving the subject of these exhibits some mention must be made of the motion pictures. The scope and variety of these can best be suggested by the fact that three theatres were in continuous operation, and each was showing something in the neighbourhood of twenty films a day.

The enormous size of the Convention Hall (its floor space would engulf St. Paul's Churchyard), and the equally enormous wealth of many of the firms exhibiting, combined with native American flair for advertising, produce an impression of colour and luxury which would be startling, even shocking to post-war English eyes. It is of course impossible to know the total amount of money spent to produce these stands but unofficial estimates varied between three and five million dollars.

One firm demonstrated the advances in a century of anaesthesia by means of a mechanical puppet show, complete with drop curtains and instrumental overture. The curtain gave up upon an operating theatre where an anaesthetist explained the progress of anaesthesia to one of the original A.M. delegates who has returned to this world for a brief look round. The demonstration is remarkably complete, even to the movement of the puppet's arms, head, and lips, and the lecture illustrated upon a miniature screen. The manufacturers state that it is "the expressed opinion of many of the visiting surgeons that this exhibit is a museum piece." It seems fitting comment.

Summaries of Papers

NITROGEN MUSTARDS

Drs. Leon O. Jacobson and Charles L. Spurr, of the University of Chicago, read a paper on nitrogen mustards in the treatment of disease. Developed originally as poison gases, nitrogen mustards have been used with encouraging results in the treatment of Hodgkin's disease. Fever, pruritus, and malaise are frequently relieved within a few days of treatment, and there is slow regression in the size of the liver and spleen and the enlarged lymph glands. Nitrogen mustards, according to Drs. Jacobson and Spurr, have produced significant clinical remissions in Hodgkin's disease, lymphosarcoma, chronic lymphatic leukaemia, chronic myelogenous leukaemia, and polycythaemia rubra. The drug was without effect in acute leukaemia and multiple myeloma.

CANCER OF THE STOMACH

Dr. Owen H. Wangensteen, of Minneapolis, observed that (1) cancer of the stomach was the most frequent of all malignancies; (2) that the death rate from it was high in almost all countries, comprising 25-40% of all deaths from cancer; (3) that in the U.S.A. cancer as a cause of death ranked next to heart disease and that of the 150,000 annual deaths from cancer approximately 40,000 resulted from cancer of the stomach; (4) that at present the only worthwhile treatment was surgery. Many patients with cancer of the stomach were inoperable when they first consulted the physician; only 25% were "suitable candidates for a curative type of operation." Dr. Wangensteen considered the problem was to persuade men and women who had reached the "cancer years" to undergo periodic examination. Figures indicated that one woman out of every five past 40 years of age would die of cancer and one man out of every six past 50. He urged the setting up of cancer detection clinics at strategic places manned by competent specialists in the various branches of medicine and surgery.

VIRUS DISEASES

Dr. Edwin W. Schultz, Professor of Bacteriology at Stanford University, California, said that viruses had a wide variety of hosts. The discovery by Dr. E. W. Goodpasture that the developing egg could be used as a growth medium for viruses was a milestone in the study of these organisms. Also of great importance was the electron microscope and the use of colloid filters for classifying viruses according to size. The difficulty of treating virus disease in man lay in the fact that a virus particle, once lodged in a cell, was apparently out of reach of drugs which might be carried by the blood stream, while antibodies were too large to follow the virus into the cell. Recently reported results following administration of sulphonamides and penicillin in certain individual virus and rickettsial infections suggest that such an approach may not be entirely out of the question," he said. Effective immunization against many virus diseases seemed to require the use of active virus, but strains safe enough for use as vaccines were few in number. Vaccine virus, fixed rabies virus, and strain 17D yellow-fever virus were three outstanding examples.

In a paper on the electron microscope Dr. Ralph W. G. Wyckoff said that magnification by as much as 100,000 times could be obtained. "The largest viruses have distinctive shapes. Some are brick-like, like the poxes. Some bacteriophages are perm-like with heads that show characteristic internal structures and tails whose appearance depends on the strain. All the very small animal viruses and most of the plant viruses thus far photographed are spherical or nearly spherical particles."

IDIOSYNCRASY TO DRUGS

Dr. Carl A. Dragstedt, of Northwestern University Medical School, Chicago, in a paper read before the Section on Experimental Medicine and Therapeutics, said that idiosyncrasy to certain drugs represented one of the most challenging of all problems in medicinal therapeutics. There was no satisfactory explanation as to why some people became allergic to certain drugs and some people did not. "Experience has taught us that idiosyncrasies to aspirin, aminopyrine, the organic arsenicals, the sulphonamides, thiouracil, quinine, and many others, are considerably more frequent than to alcohol, amphetamine, ascaral, chloral hydrate, digitalis, and the like; but there is little ground for any generalization that would have prophetic value as to the potentiality of idiosyncrasy for a hitherto unknown drug."

X RAYS AND WOUND INFECTION

Dr. James F. Kelly, of the Creighton University School of Medicine, considered there was no justifiable reason for not using x-ray irradiation for the prevention and treatment of wound infection. It was simple, and cost little. The dangers from such application of the rays were less than the dangers associated with many other forms of prophylaxis or therapy. The application of x rays in acute infection was followed by favourable clinical reactions—decrease of pain, localization of the infection, conservation of tissue, prevention of secondary infections, and shortening of the course of the disease. He claimed that x rays had proved very effective in the treatment of gas gangrene: in a group of 46 cases treated by x rays but receiving no serum the mortality was 4.34%.

PEPTIC ULCER

Sir Heneage Ogilvie, reviewing the treatment of peptic ulcer, observed that "whatever we wish to believe regarding stomach ulcers, we can find evidence in experimental work to prove theory." The only factor on which there was unanimity of opinion was the part played by hydrochloric acid. Peptic ulcers were common where hydrochloric was high, rare where it was low, and unknown where it was absent. It had been estimated that in the U.S.A. 6,500,000 persons suffer from peptic ulcer.

Dr. Samuel F. Marshall, of the Lahey Clinic, Boston, said that over a 10-year period there had been in his clinic approximately 8,000 peptic ulcers with a ratio of 10 duodenal ulcers to one gastric. He urged that operation should be performed whenever a diagnosis of gastric ulcer was in doubt. "We believe that all patients with chronic or recurring gastric ulcers

should be operated on without delay because of the considerable percentage of diagnostic error and because resection can be done with so great a margin of safety." Early recognition of cancer of the stomach presented a challenge to the medical profession, because in many cases the diagnosis was made too late.

Dr. Maurice Feldman, of Baltimore, in a paper entitled "A Statistical Study of the Life Cycle of 1,154 Cases of Duodenal Ulcer," stated that although the cause was still debatable there was no doubt about the association of psychogenic factors. In the majority of cases of duodenal ulcer symptoms began between the ages of 20 and 35.

The psychogenic factor in peptic ulcer was stressed by Drs. Jurgen Ruesch and Karl M. Bowman in a paper on personality and chronic illness. "We have been able to show," they stated, "that in chronic disease in general, in duodenal ulcers, and in thyroid patients, there is an unusual number of social climbers and strainers. . . . In ulcer and thyroid patients in particular there was an unusual incidence of foreign-born and native-born persons of foreign parentage. This fact would indicate that culture change and the resulting conflict of values were a source of stress and strain in these patients."

PSYCHOTHERAPY IN PRACTICE

The importance of psychotherapy in general practice was emphasized in papers read by Dr. Edward Weiss, of Philadelphia, and by Dr. Walter C. Alvarez, of the Mayo Clinic. Dr. Weiss defined psychosomatic medicine as "the simultaneous application of a study of the patient's mental and physical life." Although "psychosomatic" was a new term it described an approach to medicine as old as the art of healing itself. "In our elaborate medical institutions," Dr. Weiss observed, "with a lack of knowledge of the patient's background, we over-emphasize the so-called scientific aspects of medicine and relegate to the background the social and emotional factors that may enter into illness. As a consequence our methods of taking a patient's medical and personal history have not kept pace with general progress in medical science." He emphasized the value of the service given by "the old family doctor" who "relied heavily on psychosomatic techniques even if he didn't know it." He urged that the doctor intending to go into general practice should have more training in psychiatry.

LIQUID OXYGEN

The use of liquid oxygen in skin disease was discussed in a paper read by Drs. Roy L. Kile and Asbton L. Welsh. Liquid oxygen was applied by cotton wrapped around a wood applicator. Liquid oxygen was inexpensive and, with reasonable care, safe to use. It was easier to handle than was carbon dioxide. Liquid oxygen was so cold that the lesion rapidly turned white. A thorough freezing of the lesion occurred in a few seconds. With it they had treated warts, haemangiomas, leucoplakia, seborrheic and senile types of keratosis.

LONGEVITY AND MORTALITY OF AMERICAN DOCTORS

A preliminary report on the longevity and mortality of American physicians from 1938-42 was made by Dr. Louis I. Dublin and Mr. Mortimer Spiegelman, of the Metropolitan Life Insurance Company. According to these two statisticians the average young physician entering the profession at the age of 25 has 43½ years of life in front of him. On reaching the age of 35 the physician on an average has almost as many years remaining as he has already lived. At the age of 45 he may expect a further 25 years of life. "Almost 12 additional years of life remain to the average physician attaining the age of 65, a frequent age for retirement."

The insurance company's study is based on records of living physicians and on the deaths of active and retired physicians for the period 1938-42. The general conclusion was that "physicians experience practically the same longevity and mortality as white males of the same ages in the general population." Knowledge of hazards to health give physicians an advantage. "Evidence in this direction is found in the favourable mortality for most infectious diseases and surgical conditions and from accidents. The death rate from tuberculosis among male physicians is less than half that of white males of the same ages in the general population; for syphilis the ratio

is only one-third. The death rate from cancer among male physicians is four-fifths of that for white males of the same ages; in the case of appendicitis, hernia, and intestinal obstruction the ratio is three-quarters. . . . These advantages are offset by a relatively high mortality from the cardiovascular conditions. In particular the recorded death rate from diseases of the coronary arteries among male physicians is $1\frac{1}{2}$ times that of white males of the same ages in the general population." Mortality from leukaemia among male physicians was found to be $1\frac{1}{2}$ times that of white males generally. Dr. Dublin and Mr. Spiegelman repeated the opinion recently expressed that physicians may have acquired the disease as a result of exposure to x rays. "Far outstanding on the mortality list are diseases of the heart and coronary arteries, with 40.7% of the total deaths."

CANCER DETECTION IN AMERICA

[FROM A CORRESPONDENT]

The very high proportion of cases of malignant disease which are inoperable when seen for the first time in a hospital out-patient department is surely a challenge to the medical profession, whose responsibility it is to take all possible steps to improve this state of affairs. In the United States of America this challenge has been accepted and an attempt is being made in many parts of the country to extend the principles of preventive medicine to the control of cancer.

There are two complementary efforts: first, an educational campaign to bring to the notice of the public the early signs and symptoms of the more commonly occurring types of cancer; secondly, the provision of clinics at which people whose interest has been aroused may be given a thorough examination. The object of the publicity campaign is not only to persuade people who have signs or symptoms suggestive of malignant disease to seek immediate medical advice, but equally to persuade apparently healthy people to undergo periodic physical examinations as the best means of achieving early diagnosis and treatment of malignant lesions. The clinics are usually known as Cancer Detection or Prevention Clinics, and are held at fully equipped general hospitals which provide radiological and laboratory services and, most important of all, well-trained clinicians. They are in most instances run quite separately from the established tumour diagnostic clinics in order to encourage regular visits from normal or presumably normal individuals.

The patient, after a detailed clinical history has been obtained, is given a complete physical examination which includes the mouth and nose, the rectum, and in women patients the vagina. Laboratory tests such as a urine examination, a complete blood count, and a Wassermann reaction are routine. X-ray examinations are carried out whenever the slightest symptom suggests their need, and in many clinics it is hoped to make an x-ray examination of the chest and alimentary tract a routine when wartime shortages of material and staff have been overcome. The clinics do not undertake treatment; if the examination reveals a malignant lesion or some constitutional disease the patient is referred with a full report to his medical practitioner or, if he so prefers, to the proper department of the hospital. Patients in whom no malignant lesion is discovered are instructed to return for re-examination in from six to twelve months or earlier if any unusual symptom appears.

Results of the Scheme

The success of the publicity campaign is shown in the published figures of the patients attending the Strang Cancer Prevention Clinic at the Memorial Hospital, New York: 40% were referred from the New York City Cancer Committee, 30% through various types of publicity such as lectures or demonstrations, 16% were referred by former patients, and 10% came from the Memorial Hospital clinics. From the medical point of view the results of the experiment are equally encouraging. It was found that out of a total of 1,103 cases attending the Strang Cancer Prevention Clinic 7% had malignant tumours. In the group of patients reporting without symptoms and apparently healthy 1% were discovered to have malignant tumours. A considerable proportion were found to have other

diseases which required treatment. Dr. L'Esperance, Director of the Strang Clinics, insists, not without reason, that in discovering unsuspected lesions such as rectal adenomata and cervical tears and erosions the clinics are helping to prevent the development of cancer. These clinics are now well established in the public esteem and they have received the official blessing of the American Cancer Committee. In New York the medical students at the Cornell Medical Centre attend the Cancer Prevention Clinic at the Memorial Hospital as part of their studies in preventive medicine.

These are the bare facts. Armchair criticism may be levelled at many aspects of the scheme, but it cannot be denied that essentially the scheme provides the only way in which the medical profession can hope to discover an increasing proportion of cases of malignant disease at a stage in which a cure is not only possible but probable. It may be rather terrifying to contemplate the snowball growth of these clinics, but in return we may hope for an increasing number of patients who have been cured of cancer and are not afraid to tell their friends about it.

RADIOTHERAPY OF CANCER

Radiotherapy centres are still suffering from the dislocation caused by the war and from uncertainty as to future developments under the National Health Service Act. The National Radium Commission in its report¹ for 1945-6 urges strongly that in every region there should be a cancer organization, under the regional hospital board, to provide facilities for early diagnosis readily available to every general practitioner, and for immediate treatment planned and carried out by experienced specialists. Every patient suffering from cancer, whether seen in the early stage or in the late stages of the disease, should be followed up at intervals until death from whatever cause.

The report points out that these regional cancer services should not be difficult to set up as the Commission had such schemes in view from its inception. Some regional planning has been done already in the areas where national or regional radium centres exist, namely, Birmingham, Bristol, Bradford, Cambridge, Cardiff, Leeds, Liverpool, Manchester, Newcastle, Sheffield, and Southampton. For other parts of the country it will be more difficult because of the scarcity of specialists and the difficulty of persuading some surgeons "to abandon the present haphazard method by which one surgeon tries to deal with a great variety of types of cancer."

The Commission has paid special attention to the position of the general practitioner in such a service and to local organization designed to facilitate early diagnosis. The British Empire Cancer Campaign has been asked to arrange for lectures to general practitioners. The record cards which have always been insisted on as a condition for the loan of national radium have now been taken over by the General Register Office at Somerset House.

The report contains short summaries of annual reports from most of the centres connected with the National Radium Commission. If these are compared year by year it will be seen that the Commission has had a profound influence on local organizations for the diagnosis and treatment of cancer, the good effect of which is just becoming obvious.

Diabetes: A Concise Presentation. By Henry J. John, M.D., F.A.C.P. (Pp. 300; illustrated. 17s.) London: Henry Kimpton. 1946. Consisting of a series of papers on diabetes, this book will not satisfy the student seeking a clinical description of the disease, for symptoms are regarded as belonging to the pre-insulin era, and reinitis, a complication seen only too often in patients having the best modern treatment, is not mentioned. The calculations necessary for the generous diets advocated are too complex for use in countries where food is rationed and leisure small, and the author does not describe recent work on carbohydrate metabolism. Though his observations—based on wide experience—are interesting, this book cannot be classed with standard works on the subject. However, he discusses with homely wisdom the special problems of the diabetic patient, and is at his best in writing of the diabetic child.

Nova et Vetera

AMATEUR BODY SNATCHERS

William Merritt Hartlebury Day, M.D., qualified at St. Peter's Hospital, Bristol, and was a student there from 1834 to 41. Dr. Day was surgeon at Wells County Asylum in 50 and later medical superintendent at Stapleton (Bristol) Asylum. He died on Aug. 9, 1871. Recently his granddaughter, Miss Kathleen Tittle (Director of Music at Howell's School, Denbigh, N. Wales), sent us a manuscript in his handwriting. This is signed "W. M. H. D." and dated March 10, 1835. It is given in full below and has been altered only by punctuating and paragraphing.

A Visit to the Tombs

Being one evening in a pensive and thoughtful mood with nothing to do I sat me down with a determination of writing particulars of my first visit to the tombs. My fellow apprentice and myself having determined upon having a subject for dissection we accordingly prepared for our adventure, which with ourselves a friend and a man we hired to dig we proceeded. Having got every thing that our share required—mean tools, spade, sack, etc., and with two bottles of shrub and a small stick—we thought ourselves a match for any harley or charleys that by chance we should happen to meet. Having a good tuck in and plenty of strong beer we thought about 11 o'clock time to start, so off we sallied to the churchyard merry and not fainthearted. But I, unlucky fellow as I was, was, and so will be till the end of my days, lost the cork of one of our grog bottles, which occasioned us to drink on our passage. We all arrived without further interruption in the churchyard, when we waited close by in a convenient place while one of our company proceeded to the churchyard and having looked about him and seeing all was favourable he came back and we all sallied in together. The man then commenced digging, I and another was watching at a distance and the other was waiting by the man to help him when he wanted help.

Soon after our arrival a shower of mist began to fall which greatly favoured our work. I felt myself quite warm and without any dread or feeling in the place I was in. I walked about when it was time to watch with the greatest composure. The clock struck 12 and we all stepped back to the hedge and waited. I forgot to state that there was a path through the churchyard which the watchman had to walk through in going round every half hour. So you must think it was bold proceeding for four young chaps who was never out before or had an idea as to the manner in which such work was performed. So waiting nearly half an hour for the watchman the man then began to swear and said he would not wait any longer, so he accordingly went to the grave which was by the short path and recommenced digging.

The clock struck one, two, then three. No hopes of finding anything like a coffin. The grave was two feet deep in water. The man then began to swear in a horrid manner and said he would not go on, but at last with frequent tips at the shrub and doing a bit now and then ourselves got the better of him. We at last came to a coffin, which to our great disappointment was a child's; it had intact coverings with a silver edge to it. We accordingly commenced lift the lid, which we found was like a bit of soaked leather, resisted the chisels and very effort which we tried to move it. We accordingly after

long time made a small opening, which with our hands we were bit after bit till at last we made an aperture big enough to pull the little dog through; he looked more like a drowned rat when I got hold of him to pull him out of the grave. We accordingly put him in the sack and we recommenced the business of filling up the grave.

There was a watchbox adjoining the wall of the churchyard, in which two watchmen. One of our company went up to the watchbox to listen if he could hear the men digging, which he said he could quite plain. While he was standing there two cats came upon the wall and commenced caterwauling in a dreadful

manner, which made him run off. During the time we was there the weathercock kept veering round with a terrible noise as if angry at our proceedings. After we had put the subject in the bag we commenced filling the grave, which the time we was there, the time of the morning, and the disappointment we had felt in not finding a full-grown subject, after we had filled the grave we determined upon leaving the grave half filled up and returning home. We got all our things in order and left the churchyard, and as we got outside the gate, the man carrying the body and I last with the spade, to our utter astonishment and terror we beheld two watchmen standing staring us in the face, but they, although they must have seen us as plain as I see the paper I am now writing upon, never offered to move. We expected to hear them spring their rattles every minute; we accordingly without further interruption proceeded homewards, and when we arrived the person that was to wait up for us that went to sleep and we accordingly, because we should not make too much noise as the watchmen were going their rounds, we placed the body in the niche of our door and the spade in another. We placed our backs against the door and in it went. We brought in the body and things and found it was six o'clock. So we had been five hours in the churchyard.

About eight o'clock I and the man and my fellow apprentice proceeded homewards with the body, which we had in a sack, the people staring at us as we went along the street. We left the man about half way and we went ourselves with the body; the shops were by this time opened and the business of the day had begun. We were covered from head to foot with churchyard dirt, which made us look very suspicious; every person that passed staring at us well as much as if they suspected we were murderers. When we arrived home no one was up and we had to wait till we had knocked them up. Our fears had not ended then, for by the time we had arrived a dog was took ill with convulsions and began moaning in a dreadful manner and a crowd soon collected round the door, which looked more at us than at the dog. I should have done the same myself seeing two young fellows standing at a surgeon's door with a sack on their back covered with red mud from head to foot looked damned suspicious. At last the door was opened and went in with our sack. Thus ended my first visit to the tombs.

March 10, 1835.

Preparations and Appliances

PNEUMATIC BONE SAW

A pneumatic bone saw made by Desoutter Brothers Ltd. is now more freely available. This is not a new instrument. It has been used at selected orthopaedic centres for some years, and with increasing experience a number of minor modifications and improvements have been made. Experiments with this

"Mighty Atom" pneumatic bone saw were first undertaken because of the wartime shortage of imported American electrical bone saws. The pneumatic motor used in the instrument is a development of that used in a series of aircraft tools.

All gears and rotating parts are made from chrome-nickel steel, hardened and tempered, and every bearing is a ball or roller bearing. The bone saw is supplied in a wooden case with a 10-ft. length of special high-pressure hose and a quick-coupling unit, chuck key, three stainless steel spindles fitted with stainless steel saws (1 in., 1½ in., and 1¾ in. in diameter), and a spanner for changing saw blades. The tool weighs 1½ lb. and will cut bone grafts with single or double saws. The speed is controlled by a trigger in the pistol-grip handle and the range is from a few rotations to the full speed of 2,000 r.p.m. The saw has to be sterilized by hot air and cannot be boiled or sterilized in the normal steam autoclave. It is worked from compressed-air cylinders with a reducing valve, and a 100 cu. ft. capacity cylinder will give approximately 20 minutes' continuous running—sufficient, that is, for several operations. Over fifty of these instruments have been in use now for a considerable period, and independent orthopaedic surgeons have referred to the pneumatic bone saw as "first-class" and of "proved merit."

Reports of Societies

PHYSIOLOGY OF THE BREAST

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on June 20, with Dr. JAMES WYATT in the chair, three papers were read dealing with recent developments in the knowledge of the physiology of the breast.

Dr. S. ENGEL, discussing the anatomy of the female breast in its relation to hormonal response, said that anatomical and histological investigations had been carried out on some 80 breasts in the resting and active stage. In many cases large sections through whole breasts had been used on account of the variations in any single breast. It could be shown that the mammary gland in man differed from that in animals. In animals the breast was filled to capacity with glandular tissue when lactating, whereas in man there occurred many variations, ranging from almost nothing to animal-like abundance. Approximately one-third of the breasts examined had proved to be well equipped; about one-third were below the average, and the remainder showed many transitional stages. Clinical experience of lactating capacity accorded with the anatomical figures.

Badly equipped resting breasts showed primitive and badly differentiated glands. These glands responded poorly or not at all to hormonal stimulus, as could easily be seen in menstruation. Well or less well differentiated glands of the same organ showed different reactions—that was to say, rich sprouting in the first case, and no reaction, or almost none, in the second. This behaviour accounted for the divided opinion on the changes of the resting breast in the menstrual cycle, illustrating the fact that women with well-equipped breasts showed clinical and anatomical changes, whereas others remained indolent. The conclusion was that menstrual changes in the breast might or might not occur. In pregnancy the development depended on the congenital nature of the breast, since hormonal stimulus could not do more than mature what was present in the resting breast. The hormonal treatment of hypogalactic women was therefore limited, for it could only help to bring the mammary gland to its maximal production; it could not convert a poor breast into a good one. Briefly it could be said that the mammary gland in man differed so greatly that its variations had to be taken into account when speaking of hormonal influences. The badly equipped breast would not respond at all, or very little, in menstruation. The presence or absence of clinical symptoms in menstruation would serve to estimate and predict the capacity of lactation in individual cases.

Dr. J. S. FOLLEY said that the first requisite for successful lactation was the existence of adequately developed mammary glands, which presupposed the presence of sufficient histologically normal alveolar tissue. Mammary growth was under the control of the ovarian hormones, oestrogen and progesterone, but it was not possible to make any satisfactory generalization regarding their respective roles in mammary growth, since experiments on various species had revealed striking differences.

To summarize the main experimental findings: it was seen in some species, such as the mouse, rat, and rabbit, that oestrogen alone, in physiological doses, evoked growth of the duct system but little or no alveolar development. In order to produce the latter, combined treatment with progesterone and oestrogen was necessary. In species such as the guinea-pig oestrogen alone was capable of evoking the growth of duct and alveolar tissue alike; it could develop a gland which, under suitable conditions, was able to produce considerable quantities of milk, as shown by the fact that male guinea-pigs in which mammary growth had been brought about by treatment with oestrogen would rear young. The most spectacular results in this category had been obtained in ruminants. In 1938 De Fremery had shown that treatment with natural oestrogens would produce considerable udder development in virgin goats, and it had since been discovered that in the virgin heifer suitable oestrogen treatment would cause the growth of udders capable in many cases of secreting economically important yields of milk. Later experiments done on ovariectomized ruminants indicated that successful results did not depend on the presence of the ovary. In general the response was not quantitatively comparable to a normal lactation, which at once raised the question of whether such experimentally developed glands were normal in structure, and it seemed possible that some additional endocrine stimulus acting in conjunction with the administered oestrogen was necessary for the artificial development of glands capable of yielding amounts of milk such as would be obtained in a normal lactation.

"Galactopoiesis"

So far consideration had been confined to the phenomenon which might be described as lactogenesis, or the initiation of lactation. There was an allied but not necessarily identical phenomenon, the stimulation or augmentation of lactation already established, which it had been suggested might be described as galactopoiesis. It seemed probable that the treatment of deficient lactation in women fell under the latter heading, since in most of such cases lactation had been initiated but the milk yield had failed to reach a level necessary for the adequate suckling of the infant. The discovery of the anterior pituitary lactogenic hormone, prolactin, by Stricker and Gruete in 1928, and its subsequent characterization by Riddle and his collaborators as a pituitary hormone distinct from other pituitary hormones then known, and specific in its ability to cause growth and secretion of the pigeon-crop gland, aroused interest in the possibility of stimulating lactation, particularly in cows and women, by anterior-pituitary extracts. With the development of methods for the partial purification of prolactin there was some tendency to assume that purified prolactin preparations would prove more efficient as galactopoietic agents than unfractionated anterior-pituitary extracts. Extensive experiments on cows, however, had shown that, far from this being the case, unfractionated ox anterior-lobe extracts gave considerably greater galactopoietic responses in cows in declining lactation, for a given unitage of prolactin as measured by the pigeon-crop tests, than partially purified prolactin preparation. With crude saline extracts of ox anterior pituitary substance, though temporary, increases in the milk yield of cows in declining lactation could be obtained even in response to single subcutaneous injections. With repeated injections a more sustained, but still temporary, response was obtained.

Finally, there were the effects on lactation of administration of thyroid hormone. The main features of the galactopoietic effect resulting from thyroid treatment might be briefly summarized as follows: The increase in milk yield during the period of treatment was considerable and might amount to as much as 30% above the basal level. Overdosage with thyroid preparations leading to a condition of marked hypermetabolism might, on the other hand, decrease the yield. Most workers have observed, *pari passu* with the enhancement of the milk yield, increases in both the fatty and non-fatty fractions of the milk solids; the increase in the non-fatty solids content was at the best slight, but the fat content underwent a more marked increase, sometimes to as much as a 50% rise in the daily yield.

This work had assumed importance from the point of view of wide-scale practical application in the dairy industry where

was shown that treatment of certain proteins, such as casein, with iodine under mildly alkaline conditions produced iodoproteins which exhibited thyroid activity by the oral route and from which thyroxine could be isolated after hydrolysis. Since docascin could be made quite readily from available materials it was evident that here was a cheap and plentiful supply of thyroxine. It was also shown that the thyroid gland of the rat could be made to produce thyroxine in all essentials by feeding iodoprotein. One important point was that prolonged feeding of doses sufficient to produce milk yield increases of the order of 30% above basal caused sufficient hypermetabolism to bring about significant and undesirable losses in body weight. If, however, one contented oneself with smaller responses the body weight losses were negligible, provided extra food was given as a compensation. Clinical reports on the use of thyroid hormones for the stimulation of lactation in women had not always been favourable; in fact, some clinicians had advocated thyroid treatment for the suppression of unwanted milk secretion. Nevertheless, further clinical trials, keeping the necessity for careful control of dosage in mind, would appear to be justified.

Vitamins in Human Milk

Mrs. MAWSON and Dr. S. K. KON read a paper on the study of certain vitamins and other constituents of human milk. The investigation described had lasted for more than four years, during which period 2,000 samples of breast milk were examined. Owing to the food policy of the Government some of the changes they had noted had been for the better rather than the worse. They had taken Reading, a prosperous town in an agricultural area, as a starting-point in the early summer of 1941; and in April, 1942, they had obtained support from the Medical Research Council which had enabled them to extend their activities to Shoreditch, thus providing a good contrast. In both areas the husbands of many of the mothers were in the Armed Forces, but Shoreditch had been more subject to enemy attacks than Reading. As a result of the work done confidential reports were sent each year to the Medical Research Council, and from these had followed certain important changes in wartime diet. The difference in the analysis of the milk was most noticeable immediately after the introduction of "national" wholemeal bread and also the first consignments of oranges to reach this country during the war.

Mr. BOURNE mentioned that one of the difficulties that Dr. KON and Mrs. MAWSON had encountered had been to discover women who were sufficiently ill-nourished to provide a really substantial difference in dietary intake compared with those on normal feeding; but there had been one woman found who was grossly undernourished, and it would be interesting to learn what differences were found in the composition of the milk. He had noticed tables on the screen showing the differences between cow's milk and human milk, and he had seen elsewhere attempts to supplement the milk in order to give the child the theoretical optimum. He thought that all such treatment of the natural product was nonsense, and that the more the child had of the natural milk the better it would be. Dr. KON, in reply, said that with regard to the woman who was grossly undernourished the composition of the milk had been found to be perfectly normal, and it was also found from milk samples in Belgium and Holland taken immediately after liberation that this was usual. They had had to revise their ideas of the effects of starvation and shortage of calories and essential foodstuffs. At such a low level life was geared down so that they could run satisfactorily with a less output of energy.

The Association of British Chemical Manufacturers has issued from 166, Piccadilly, London, W.1, the 1946 edition of its directory *British Chemicals and their Manufacturers*. During the war years the Government forbade publication of new editions and this is the first revision of the directory since 1939. A copy will be sent gratis by the manager of the A.B.C.M. to any inquirer writing on business paper or giving other genuine indication of his being likely to put the directory to good use as a purchaser of chemicals.

Correspondence

The Physiology of Vision

SIR.—I have read with great interest the leading article (June 28, p. 932). There are two points which I would like to raise.

In the first place, my doubts concerning the validity of the three-colour theory do not rest entirely on research in which it was necessary to confine the stimulus to single cones or to small clusters of functionally identical cones. Thus one experiment requiring no apparatus, which can be performed by anyone in an ordinary room, consists of taking three little coloured test objects 5-mm. square each—a bright red, a bright green, and a lemon yellow. These are separately mounted in the middle of pieces of black paper about 20 cm. square. If these are examined at a distance of perhaps 5 metres to 10 metres—this distance varies somewhat with the intensity of the light and the personal equation of the observer—it will be found that the yellow test object has altered to pale grey or white, whereas the red one and the green one have retained their colour, with hardly any observable alteration. Now, on the three-colour theory yellow is a mixture of red and green; therefore it would be expected that all the three test objects would undergo changes at about the same distance, but this they do not do. If this experiment be repeated with monochromatic lights produced by a spectroscope a similar result will be obtained.

This was the first experiment that shook my belief in the three-colour theory, to which I had always been a strong adherent.

The second comment concerns Dr. Willmer's book. The writer of the leading article considers that it supports the three-colour theory. A careful examination of this book shows, however, that this is not the case, for it describes an essentially dichromatic hypothesis. This is shown with great clearness if the figures illustrating chapters III and IV are examined. It is true that he states here and there in the book that the dichromatic hypothesis as it stands appears to be inadequate, and that some other factor must be involved of which no account has so far been taken; but in every case he follows it by some such statement as: "There is at least the possibility of overcoming the difficulty under consideration, without immediately assuming the existence of another distinct type of receptor." Thus nowhere in the book can one find anything to suggest that Dr. Willmer wishes to abandon entirely the dichromatic hypothesis which he advances in such detail.—I am, etc.,

London, E.C.1.

H. HARTRIDGE.

The "Costoclavicular Syndrome"

SIR.—As co-author with Graham Weddell of a paper¹ in which the term "costoclavicular compression" of the subclavian vessels was introduced to the literature, and which is one of the two papers specially mentioned in the text of the recent article in your columns on the "costoclavicular syndrome" by Telford and Mottershead,² may I be permitted to forward my comments? I trust you will forgive the delay, but the issue containing this paper has only recently arrived in this country.

Prof. Telford and Mr. Mottershead have rightly stressed that no one mechanical cause can explain all cases of pressure symptoms involving the neurovascular bundle at the base of the neck, and to this view I subscribe. They conclude that under certain circumstances costoclavicular compressions may occur, but in spite of an exceedingly rich experience of cervical rib syndromes they do not appear to have recognized a single example of costoclavicular compression, and consequently leave their readers with a feeling that the syndrome is mere supposition.

Compression of the subclavian artery between the clavicle and an unusually placed first rib has now been seen at operation by a number of observers³⁻⁵ besides ourselves. We described a case with vascular symptoms in which, at operation, proof was forthcoming that the subclavian artery was being compressed intermitently between the clavicle and the first rib, and in which symptoms disappeared completely after this costoclavicular compression had been corrected by removal of a segment of the rib. In addition

we described two other cases, one of which did not require operation, to illustrate other aspects of the mechanism, and also a fourth case with nervous symptoms to show that the mechanism did not operate in all cases with rib-pressure symptoms. Our primary purpose in reporting these cases was to show that the then widely held explanation of the scalenus anticus pressure, and also that of sympathetic dysfunction due to irritation of sympathetic fibres in the lower trunk of the brachial plexus by rib pressure, were not operative in these cases. It is interesting to note that the second of these explanations, which was championed by Prof. Telford on several occasions between 1913 and 1942,^{1,2} is not mentioned, either in support or refutation, in his latest article.³

Telford and Mottershead quote us that "more than one postural manœuvre involving the shoulder girdle may result in compression of the subclavian vessels," and then in the same paragraph go on to describe the effects on the pulse of depression or downward movement of the shoulder. We, however, had pointed out that "backward and downward bracing of the shoulders is the motion which most directly approximates the clavicle to the first rib," and illustrated the backward mechanism with a line diagram. Nowhere did we describe pure depression of the shoulder. This is important, as Telford and Mottershead take pains to show that pure depression of the shoulder widens the interval between clavicle and rib, although later in their paper they concede that backward movement or retraction of the shoulder may produce clavicular pressure against the scalenus medius. Their movement of retraction had an upward component, however, and if instead a downward component could have been imparted the clavicle would have approximated to the rib. Their findings were based largely on observations in formalized corpses, and must therefore be accepted with reservation. Only five fresh post-rigor bodies were tested, and, as in another part of their article they showed that retraction of the shoulder only affected the pulses in 60% of living persons, this number of fresh bodies is too few to prove the non-existence of costoclavicular approximation. Their statistics would have been of more worth had they, like ourselves, tested for costoclavicular approximation on the operating table in patients on whom it had previously been shown that retraction of the shoulders obliterated the pulse.

In describing depression of the shoulder Telford and Mottershead point out that, though the pulse in the arm may disappear on depression of the shoulder, a normal pulse remains in the axillary artery well below the clavicle, and that the clavicle consequently has nothing to do with the arrest of the pulse in this manœuvre. This I have confirmed in a few subjects whom I have just tested, but I have noted also that when the shoulders are braced backwards and downwards and the radial pulse disappears even the pulsations in the axillary artery cease. The arrest of the pulse in these two manœuvres, therefore, must be by different mechanisms, and thus the throttling of the brachial artery by the two heads of the median nerve, which Telford and Mottershead describe as occurring in depression or downward movement of the shoulder, is presumably not the responsible mechanism in retraction of backward movement of the shoulder. This latter mechanism we believe to be costoclavicular approximation.

As a cause of symptoms, the costoclavicular mechanism may not be common, at least in the type of case which comes to operation. In our paper Graham, Weddell and I wondered whether it was the usual mechanism in cases of rib pressure where vascular disturbances predominate, as Eden⁴ had suggested earlier. Cases of this type with symptoms warranting operation, however, are uncommon, and I have not encountered another case at operation since we wrote our paper. Prof. Telford⁵ reported in 1942 that he had collected 4 cases with vascular symptoms out of 92 patients operated on for symptoms of cervical rib, although by 1947 his total appears to have risen to 14 cases out of 120 patients. I have, however, seen a few patients with mild vascular symptoms which I thought were caused by a costoclavicular mechanism, but they improved on exercises designed to brace up the shoulders.

As regards cases of rib pressure with nervous symptoms, I would agree with Telford and Mottershead that the great majority are due to hanging up of the brachial plexus by a cervical rib or other mechanical obstacle, such as a fibrous band or abnormally developed anterior edge of scalenus medius, for such has been my operative experience. It was with some surprise, therefore, that in 1944 I read a paper by Walshe, Jackson, and Wyburn-Mason⁶ suggesting that costoclavicular compression was also of frequent occurrence in cases with nervous symptoms. These authors, however, although they described in detail four cases with vascular symptoms, did not support their views regarding plexus compression with case histories. Consequently for some time I have regarded costoclavicular compression of the brachial plexus, in contrast to that of the subclavian vessels,

as a myth, but recently I have encountered a case. This patient a middle-aged woman, had had for many years generalized plexus symptoms of the type envisaged by Telford and Mottershead, and when the neurovascular bundle was explored at the base of the neck no abnormality other than an undue approximation of the clavicle to the first rib on backward retraction of the shoulder could be made out. The brachial plexus was then compressed between the two structures, and it is significant that symptoms promptly disappeared following resection of a segment of the first rib. It was also interesting to note that a simultaneous compression of the subclavian artery was not present in this particular case, for the planes of the two bones crossed each other obliquely, and the two bones only approached each other sufficiently to compress structures at the place where the plexus passed into the axilla.

I therefore feel that costoclavicular compression of the subclavian vessels or of the brachial plexus as a cause of serious symptoms warranting operation is a real entity, though not a common one. Any surgeon exploring the base of the neck for vascular or nervous symptoms in the arm should always search for the exact spot and mechanism of compression of nerves or blood vessels. If he cannot find an adequate cause in the more usual situations, he should insert the tip of his finger beneath the clavicle opposite the neurovascular bundle, and then by pressing the shoulder backward and downward ascertain whether a costoclavicular compression occurs. If it does the treatment is removal of a portion of the rib. Telford and Mottershead report 5 negative explorations in their series, all without relief of symptoms. Perhaps some of these were costoclavicular compressions.—I am, etc.,

Dunedin, New Zealand.

Surgery of the Gall-bladder

SIR,—I am sorry to see an error in your annotation on surgery of the gall-bladder (July 5, p. 21). You state that "partial removal of the gall-bladder, combined with electro-coagulation of the residual strip" is termed diathermy dissection. As stated in my article, this is Thorek's electro-coagulation. Diathermy dissection consists in removal of the whole gall-bladder, which is a simplification of Thorek's operation. I am afraid that anyone who reads the annotation and scans the paper will get a wrong impression.—I am, etc.,

Oxygen Poisoning in Man

SIR,—Sir Leonard Hill's correction (June 21, p. 900) of Dr. Kenneth W. Donald's attribution to the late Prof. J. S. Haldane of certain work on deep diving prompts me to this communication. Dr. Donald writes: "In 1930 the late Dr. J. S. Haldane (Haldane and Priestley, 1935) reported confusion and amnesia in deep-sea air divers at 300 ft. (91.4 m.), and these symptoms were attributed to the raised tension of oxygen. These effects were proved by Behnke *et al.* (1935) to be due to the intoxicant effect of nitrogen at high pressures."

In 1930 I was asked by the Admiralty, through the Medical Research Council, to investigate cases of supposed unconsciousness occurring in divers at 300 ft. They were not presented to me as examples of amnesia. I found the condition occurred in men already subject to unsuspected but distinctly pathological nervous symptoms. One man with severe claustrophobia had been put in a diving suit and sent down to 300 ft. By using the then unfashionable method of revival and abreaction it was shown that what the men described as unconsciousness was a state of pathological terror, the memory of which had been suppressed. The simple technique and its dramatic results were described to my colleague Surgeon Lieutenant-Commander A. E. Phillips (*Proc. roy. Soc. Med.*, 1932, 25, 693) and by myself (*Ibid.*, 1933, 26, 655). In my

ACID MILKS IN INFANT FEEDING

The wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In certain cases it is reasonable to give the infant the kind of nourishment which necessitates the least effort, and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional needs of infants requiring acid milk; the following range of products is available:—

BEURLAC

A buttermilk in powder form, useful for infants suffering from gastric disorders.

PROLAC

Of approximate half cream fat standard, but with increased protein, as required in gastro-enteritis.

LACIDAC

HALF CREAM

An intermediate grade for less severe cases and for graduation to normal feeding.

FULL CREAM

Suitable for long term use, or as a final stage of graduation to normal feeding.

SEPARATED

Almost fat free. Invaluable in cases of fat intolerance.

* Particulars of these and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request.

Vitamin Therapy—its uses and limitations

BETTER NEWS ABOUT BEMAX

Increased supplies of Bemax now being sent to Chemists should ensure that prescriptions will again be met in full. There will also be more Bemax for the priority classes, *i.e.*, expectant and nursing mothers, children and the aged, with perhaps a little left over for the ordinary consumer.

Further, the new Bemax tablets are now available and have been warmly welcomed. Containing 50 per cent. Bemax, they are a vitamin B supplement with uses similar to Bemax itself and the recommended dose provides 200 i.u. B₁—approximately the same as the daily dose of Bemax. The tablets are very palatable and are intended to be chewed.

Doctors are invited to write for a complimentary carton so that they may test the tablets for themselves.

BEMAX Stabilised cereal embryo

1 oz. of Bemax provides approximately :—

Vitamin B ₁ - - 0.45 mg.	Vitamin E - - 8.0 mg.	Available
Vitamin B ₂ - - 0.3 mg.	Manganese - - 4.0 mg.	Carbohydrate 39%
(Riboflavine) - - 0.3 mg.	Iron - - 2.7 mg.	Fibre - - - - 2%
Nicotinic Acid - 1.7 mg.	Copper - - 0.45 mg.	Caloric Value - - 104
Vitamin B ₆ - - 0.45 mg.	Protein - - - 30%

MILLAIS CULPIN.

The Measurement of Human Skill

SIR,—Prof. F. C. Bartlett's Oliver-Sharpey lectures on "The Measurement of Human Skill" published in the *Journal* of June 14 (p. 835) and June 21 (p. 877) prompt me to put down a few observations on clinical diagnosis which I believe to have a sound scientific basis. As is stated, investigation proceeds step by step, the fitting of one set of responses to another, until the diagnosis is completed. Here the conscious mind calls on the stored knowledge of the deeper subconscious levels, and between them the mystery is solved.

Now, in protective muscular reactions such as the sudden application of a car's foot-brake, closure of the eyelids, or the placing of a hand in front of the face the conscious mind has not functioned except to receive the receptor impulses. The very complicated mechanism involved in the effector response has performed its work subconsciously. Similarly in mental reactions, immediately after the receipt through eyes, ears, or fingers by the brain of a skilled clinician, the correct diagnosis may thrust itself into consciousness: the step-by-step route has been short-circuited. Before seeing the patient he is heard to cough, and in a flash "pneumonia," "basal congestion," or "tracheitis" obtrudes itself. The hand placed indiscriminately on the abdomen before inspection or the history questioned—in an unorthodox but very valuable procedure—may give rise to "appendix" or "acute abdomen." And in general practice these conditions are very rare in comparison with the number of abdomens examined, and reference here is only to obscure cases, not to those where a reasonable prediction can be made before examination. A fleeting glance at a head above the bed-clothes brings out "perforated gastric," and innumerable times a glance brings forth a sense of immediate urgency, when a subsequent more careful inspection reveals nothing startling.

It must be emphasized that these are not snap diagnoses, nor is any attempt being made to produce quick results, the performance of which is much slower and due to a completely different mechanism. Further, such practices produce a far greater percentage of error than the events described, which are almost invariably correct. These immediate effector responses occur comparatively infrequently and very erratically, but are so uniform in their characteristics as to leave no doubt as to their definite entity as a class. Their appearances bear out the statement that often the participation of the conscious mind slows down the reaction time. It is an essential that the mind be almost or entirely dissociated from the patient, in fact "wool-gathering," for the diagnosis to be presented with such precipitance.

How to measure this skill must be left to others. Its use in a busy general practice is to focus attention on a patient who needs the most thorough investigation by oneself and, if the results are not conclusive, by the appropriate consultant.—I am, etc.,

Hove, Sussex.

FRANK PORTAS.

Citrate in Urinary Infection

SIR,—Recent discussion on the use of citric acid drinks with sulphonamide therapy reminds me of the use of citrate in another sphere, whose full implication is not, I think, generally realized. Diabetics not infrequently suffer from a urinary tract infection and receive in consequence large doses of alkaline citrate. Now citrate is fully absorbed and fully utilized ("oxidized") in the body in a similar manner to carbohydrate. The method by which this occurs is, briefly, believed to be as follows: citric acid is converted to aconitic acid, which enters the "tricarboxylic acid cycle," and is converted through several stages to oxalo-acetic acid, losing two carbon atoms as carbon dioxide and releasing energy. Oxalo-acetic acid may be further decarboxylated to pyruvic acid, which may actually

be converted into glycogen, or which may condense with oxaloacetate, losing another carbon atom by decarboxylation in the process and re-forming aconitic acid, thus completing the cycle.

Now whether citrate is pictured as being converted into carbohydrate via pyruvate or as being fully oxidized in the tricarboxylic cycle is immaterial—the point being that all six carbon atoms in the citrate molecule are readily available for full utilization for the production of energy by complete oxidation, so replacing and "sparing" an approximately calculable amount of carbohydrate.

Now the two full oxidation equations for glucose and for citric acid are:

so that, taking the amount of oxygen consumed to be equivalent to the energy liberated, we have:

Assuming our patient to be getting the rather large dose of 60 gr. (4 g.) 4-hourly (which may well be needed for urinary alkalization), this means that he is having the equivalent of some 12 g. of extra sugar per day. Admittedly this is not very much when spread out over the day, but it should theoretically be taken into account in adjusting the dietary requirements of the diabetic.

This idea of the availability of citrate has other points of interest (at least in theory), such as the additional energy it presumably supplies to the ill febrile patient with anorexia who is being treated, for example, with sulphonamide, accompanied by the routine citrate; its theoretical action in checking a hypoglycaemic attack; the likelihood (on present theory) of its utilization in severe diabetics without insulin, in whom sugar is of no value.

I am very grateful to Dr. E. Baldwin, of Cambridge, for his help in regard to the biochemistry in this letter.—I am, etc.,

Wolverhampton.

W. P. U. JACKSON.

Pethidine in Labour

SIR,—I have read with interest Dr. J. H. P. Giff's letter (June 21, p. 901) stating that his experience shows the action of pethidine in labour to be unreliable. Dr. Giff does not state at what stage of labour he commences to use this drug, or any information regarding dosage, while I find that the time at which it is used is a most important factor in obtaining a successful result.

My experience with the drug, based on a very considerable and extensive usage over the past two and a half years, is the exact opposite to that of Dr. Giff: I have found the drug most reliable. The effects of pethidine in labour are helped by the previous administration early in labour (where the os is 1–2 fingers) of "seconal" 3 gr. (0.2 g.), though I have found that about 15% of patients vomit this unchanged, and I find, on short acquaintance, that "tuinal" is better.

Pethidine itself is administered hypodermically in doses of 100 mg. when the os is about 1/3 to 1/2 dilated, this dosage being repeated

if necessary hourly for three doses. If 300 mg. has no effect, I find it useless to administer more.

The administration at this stage does slow down labour for about 30-40 minutes, giving the mother rest and some sleep, after which the pains get stronger and labour is shortened, the mother being completely relaxed, and possibly asleep, between pains, but able to understand and co-operate during pains. It is worthy of note at this point that pethidine used in cases of "rigid cervix" exerts an effect which can only be described as dramatic. I have found that pethidine may safely be administered up to an hour before delivery with no adverse effects on mother or child, and after its birth, provided the cord is not cut until pulsation has ceased completely, there is no interference with the child's respiration and no cause for anxiety. If, however, it is necessary for the mother to have a general anaesthetic within this period, the induction of anaesthesia is prolonged owing to the maternal respiration being shallower than normal.

The administration of pethidine as outlined above eliminates in most patients the necessity for the Minnitt gas-and-air apparatus, which I find, even with a properly fitting individual facepiece, a most unsatisfactory and unsatisfying form of analgesia in about 55-60% of patients. In my experience pethidine used as above with premedication is eminently satisfactory in about 95% of patients and useless in the remaining 5%. There are occasionally nausea and even vomiting during administration late in the first stage, though this may be due to the onset of the second stage. There are no effects after parturition on either mother or child, and the maternal comments are most favourable and gratifying.—I am, etc.,

London, S.W.14.

A. B. WATERS.

Physical Therapy of Mental Disorder

SIR,—The recent correspondence on physical therapy in mental hospitals (June 14, pp. 861-2) has prompted me to draw to the attention of the profession a matter which, although serious and sinister in its implications, does not appear to be generally known among medical men who are unfamiliar with present-day mental hospital conditions. I refer to the increasingly common practice of inflicting on unwilling certified patients certain unnecessary and mutilating surgical procedures, particularly indiscriminate leucotomy and tooth-pulling, in a manner which is unpleasantly reminiscent of the practices of the Nazi concentration camps. The type of case in particular which I have in mind is the chronic psychotic patient under certificate in whom volition and ability to give or withhold consent are unimpaired by the disease present. In the course of several years' mental hospital experience I have seen a number of such unfortunates subjected against their will to procedures of the kind just described.

Such a practice, in my opinion, constitutes an inexcusable violation of fundamental human rights. It was pronounced to be a crime against humanity by the Nuremberg tribunal, a court composed of judges of the highest legal standing, and at the subsequent trials a number of German doctors convicted of such practices received the death sentence. The fact that the patient happens to be certified, and a form of consent is obtained from a "responsible relative," cannot, in my opinion, justify the forcible infliction of such operations on any human being; since, in my experience, the relatives of patients of the mental hospital class are as often as not even more lacking in insight and intelligence than the patient himself. In this connexion it is worthy of note that, in this as in all civilized democratic countries, even the convicted criminal is protected by law from such violation of his person.

Let it not be supposed for a moment that I am opposed to the use of physical therapy in mental disorders. My views on this subject were made clear in a previous letter in this *Journal* (May 31, p. 778). What I am opposed to is the abuses of such treatment just described, which in my opinion constitute an attack not on the problems of mental disorder but on the rights and liberties of the individual, and have contributed more than anything to bringing discredit on a new and promising form of therapy. I do not doubt for a moment that such practices are motivated by misguided therapeutic zeal rather than by wilful cruelty. Nevertheless, their sinister implication remains, and one can only conclude that they are only one more aspect of the insidious attack which is being made to-day from certain

quarters on individual rights and liberties. The German war-crime trials received sufficient publicity at the time to make a profound and shocking impression on the public conscience; yet their lesson and implications seem to have been only too speedily forgotten. Let us therefore take warning before it is too late. *Facilis descensus Averno*.—I am, etc.,

London, S.E.6.

G. TAYLEUR STOCKINGS.

SIR,—It appears that the important issue which your correspondence reflects is whether psychiatrists are going to take psychology seriously or whether they are instead going to side-step the body of analytical knowledge which has been accumulated. By confusing quick, dramatic (psychologically magical) effects with real results, they go some way at least towards disregarding the developments of the last fifty years or so. Beside this question the rest of the discussion is relatively unimportant, for if psychiatry really substituted magic for knowledge the long-term results would be disastrous to the cause of humanity.

At the present time, when most psychiatrists contrast physical therapy with psychotherapy, they are comparing a method which is familiar to them with one of which they can speak only as more or less talented amateurs. By this I mean that on the whole psychiatrists are untrained and unqualified psychotherapists (I hasten to add that there are a growing number of exceptions). It is not, however, their fault that they are untrained, since training is available only in certain regions of the country. But this should not blind us to the realities, which are very well illustrated by the assessment of results from physical methods of treatment. These are always couched in psychological terms which, to the analyst, are naive and unconvincing in the extreme. If psychiatrists unqualified as psychotherapists would openly state their lack of training or even tacitly admit it, then we should know that they are giving an untrained opinion, and we should be more tolerant of their inability to differentiate knowledge from speculation. As matters stand, there are almost bound to grow up two hostile camps in psychiatry.

As one who has seen nothing but a few bad results from physical methods of treatment, I regard myself as unqualified to make any statement about them which is not prejudiced. I will dare to say that I know more about medical and surgical methods than most psychiatrists know about psychotherapy, so that I am likely to treat these methods with the respect due to them. I invite psychiatrists to exercise a similar caution when discussing a subject they do not understand. Their lack of caution only induces feelings of disrespect and even contempt towards them, not only among our own profession but also among the better informed lay public, many of whom are able to understand the significance and value of psychotherapy in a realistic and objective way.—I am, etc.,

London, N.W.1.

MICHAEL FORDHAM.

SIR,—The letters on this subject in your columns are interesting and remarkable in displaying the prevalence of a lack of charity for the other fellow's point of view and so of an inability to understand and appreciate it. It is not surprising that the correspondence degenerates at times into an attack on mental hospitals, so that their liquidation is demanded by Dr. T. Gladstone (June 28, p. 942). Dr. Clifford Allen (p. 942) throws much light on the controversy by pointing out that practising psychiatrists for the most part see either psychotics or psychoneurotics according to the method of treatment they have become familiar with and, let us assume also, proficient in. Patients who have failed to respond to one line of treatment do tend to pass into the hands of practitioners of the other cult. There is thus a tendency for each other's failures to be seen, and a false conclusion may be readily drawn as a result.

A few of us have been fortunate enough to escape these unfortunate limitations in experience, and as medical director of an out-patient psychiatric and child guidance service and medical superintendent of a mental hospital I am responsible for providing for the needs of both groups of patients. I am associated with practitioners familiar with both lines of therapy and am in daily contact with patients undergoing both forms of treatment. Owing to the war our in-patient mental hospital side is still very greatly reduced in numbers, and although we have seriously considered leucotomy in some cases in no instance has

this been done. In this position I am convinced—at this stage I feel only personal testimony from those whose experience seems to justify its value can make a useful further contribution to this correspondence—that E.C.T. and insulin treatment have a definite sphere of usefulness as therapy at the present time and with our present knowledge.

One valuable point at least arises from the critics: effective steps must be taken to ensure that the distressing manifestations of the treatment—the sight of patients convulsed or unconscious, cry on induction, etc.—shall not be seen or heard by any other patients in the treatment unit. May I assure Dr. Allen that many of “those who use shock treatment” fully appreciate this need. From what he says it seems some still need convincing, but this is no argument against its employment with adequate precautions.—I am, etc.,

H. Albans.

W. J. T. KIMBER.

Calories and the Olympic Games

SIR,—Much, perhaps too much, has been spoken and written about our diet, and the general conclusion is that even for the ordinary person the average calorie intake is a good deal too low. Scientists, however, have had little to say regarding the necessary training diet for our athletes competing in international sport and who, next year, will be expected to uphold Britain in the Olympic Games. Yet it is clearly as unfair to expect them to compete successfully without proper feeding as it would have been to expect our Army to fight on an empty stomach.

Admittedly measurable energy used in sports is not as much as one would imagine, and an additional 500 to 700 calories could probably cover the most strenuous games (Deutsch and Lauf). But anyone who has run himself out in a mile race or played five sets of international lawn tennis or an hour's intensive squash will admit that it cannot be done without long and regular training, if the body is to be fit to fight again next day or even next week. Regular training means an intake of protein of not less than 100 g a day—the equivalent of a good steak—while Elmer Berry says that the optimum diet for an athlete includes 5 pints (2.8 l.) of milk, 8 eggs, and an ounce (28 g.) of butter a day; not to mention the oft forgotten 30 g. of salt which would stop both the cramp and a good deal of the lassitude of which our representatives at sport have recently complained.

Most foreign competitors in our sporting events are wise enough to bring their own fats and protein with them. The Australian lawn tennis team tell me they have 500 lb. (225 kg.); and of course they have had whatever they wanted to eat for many months. Whether the Government should give special allowances to Olympic and other representative athletes is, I suppose, a matter for debate; but the stomach cannot suddenly deal with increased food, and a long-term policy is the only one which would have any beneficial results. We fed our representatives specially in war: why not, one can argue, in peace? Certainly if we do not it must be a foregone conclusion that, however we may compare in technical skill with the rest of the world, we shall be unable to compete as regards stamina. That is a scientific fact that not only the public but many doctors, too, appear to miss.—I am, etc.,

London, W.1.

NEVIL LEYTON.

Penicillin for Osteomyelitis

SIR,—The development of an argument on the value of penicillin in the treatment of acute osteomyelitis is rather refreshing. The fact that time and energy are available for people to question the unquestionable implies a quiescence of the turmoil of war and a rest from the alarms of State service.

No experienced person in his or her senses could really question the value of penicillin in this condition. It has completely transformed the picture of acute osteomyelitis. Consequently I do not wish to detract in the slightest from the contribution by Mr. T. Twistington Higgins, Mr. Denis Browne, Dr. M. Bodian (May 31, p. 757), and it is unnecessary to elaborate their reply (June 28, p. 947) to Drs. J. Trueta and M. Agerholm (June 21, p. 899), which infers that nobody need take much notice of what the latter say. But I think it is reasonable to mention the importance of protecting long bones against stress. This precaution is most necessary about the end of the fourth

week, long after the temperature has subsided and healing of any wound or abscess has occurred. From that time to about the end of the seventh week decalcification necessarily resulting from the initial infection and necrosis reaches its peak, and reparative processes have not developed sufficiently to strengthen the weak part of the bone. I will not take up your space with details, but I have a vivid recollection of a child in the early days of penicillin who fractured her femur because her recovery was so spectacular that we failed to appreciate the importance of the zone of spotty decalcification.—I am, etc.,

Liverpool.

BRYAN MCFARLAND.

SIR,—We should like to change this correspondence from an argument to a constructive discussion of the best way of discovering how to obtain the fullest benefit from penicillin in acute osteomyelitis. It is clear that a number of centres working on the treatment of acute osteomyelitis with penicillin have come to different conclusions on the best method of treatment, and the variations are probably due to the relatively small number of cases which any group has treated. We suggest that the time has come for a committee to be formed to review the results so far obtained in the treatment of this disease, and to draw from the experiences of the several centres some general conclusions which could serve as a guidance for the future.

Such a committee might determine: (1) The best penicillin treatment in relation to the age of the patient, the infecting organism and its resistance to penicillin, the site of the lesion, the delay between onset of infection and the beginning of penicillin treatment. (2) The importance of the removal of pus and the best way of carrying this out. (3) The value of immobilization and the best means of deciding when it can be safely discontinued. In addition, a scheme for classifying the cases and a standardized method for recording results might be established so that different series could be readily compared.—We are, etc.,

Oxford.

M. AGERHOLM.

Leprosy and its Problems

SIR,—Referring to the leading article on “Leprosy and its Problems” (June 7, p. 813), I note two rather serious mistakes in the last two paragraphs.

1. “Nodular leprosy may possibly prove intractable.” This is entirely the opposite of the trend of my article on sulphone treatment of leprosy on p. 798. There, under “Suitable Type of Case” is written: “It is the lepromatous or severe type of leprosy to which the sulphone treatment has been applied.” The lepromatous type is the modern nomenclature for nodular leprosy, and it is this type for which the sulphones are proving so very useful.

2. The number of lepers in the world is mentioned as two million, of whom 97.5% are Indian or African. This is quite contrary to the statistics which have been generally approved. In *Leprosy* (Rogers and Muir) a table is given on pp. 13–15 which calculates 3,291,000. It is said that this is probably an underestimate, and five million is as near as we can at present get to the true figure. Of the 3,291,000, one million are given as being in China, which would, I think, be quite contrary to 97.5% in India and Africa.—I am, etc.,

London, S.W.1.

E. MUIR.

State Medical Service in New Zealand

SIR,—It is good to read in your columns (June 14, p. 865) Sir Ernest Graham-Little's substantiation of the veracity of Mr. Porritt's injunctions against the State form of medical service in New Zealand. I have repeatedly denounced the present Health Act as the progeny of an unholy marriage of the Ministry of Health and a Party medical clique. I have pointed this out as fatal to any success both in meetings of the B.M.A. and the R.C.S. The only sure foundation for a completely comprehensive and satisfying health service rests on data only to be derived from the technicians of medical practice, whose life-long job is the conversion of disease to health. The problem is abstruse and intricate. Knowledge is doubly vital for an objective of such solemn import as the health of a nation. We alone are the informed section of the community and hold the key to successful planning. Every bit of medical wisdom needs

representing, and it is incumbent upon the authorities to seek evidence from all the best brains of the profession.

There should be set up at the instigation of the Ministry of Health a new medical planning commission whose members are chosen regardless of political views but acknowledged by their colleagues as fit spokesmen by reason of their professional knowledge, vision, and humanitarian spirit. This commission would deliberate while the present Act, shorn of its controversial features, is implemented as an interim measure, and while the country is getting on its feet again.

All of us should follow Sir Ernest's line, repeat this truth, and at least free our consciences of apparent acquiescence in the degradation of a great and noble profession and its work.—I am, etc.,

Bristol.

A. WILFRID ADAMS.

SIR,—The profession owe a great debt to Sir Ernest Graham-Little for the amount of work he has undertaken regarding the national medical service.

Sir William Fletcher Shaw (May 31, p. 782) does not agree with the conclusions of Mr. Porritt and suggests that conditions in N.Z. are satisfactory to the doctors but does not give the reason. The fact is that the general practitioner receives 7s. 6d. per visit or consultation, paid by the Government, and such additional fee as he likes to charge the patient, plus mileage for visit. The doctor in N.Z. is satisfied because he is receiving not a capitation fee but a flow of income as long as he is willing to sit in his consulting room and collect the signed claim forms.

There are few queues in N.Z. except for cigarettes and the doctors. The reason there is difficulty in obtaining the services of the doctor at night and week-ends is that he is worn out with excessive work; and again nobody in N.Z. works at night or week-ends. The forty-hour week has demoralized the whole community. You are lucky to get a plumber in a fortnight. These are the views of resident doctors in N.Z.

It is suggested by Sir William Fletcher Shaw that an increase in the number of doctors will solve the problem basically due to free treatment. Does he think the doctor will be on tap for 168 hours while the rest of the community are not allowed to work more than forty hours a week by law and any earnings at night or week-end are taken over in taxation. If the doctors in this country or N.Z. ever agree to a capitation fee they will end with a State medical service.—I am, etc.,

Beckenham, Kent.

A. E. BLACKBURN.

General Knowledge and General Practice

SIR,—Dr. D. N. Baron's hobby-horse is a common one; the clacketing of its hoofs rings in our ears from student days—not that we haven't bestraddled the beast ourselves, but we have learned not to ride side-saddle. Of Dr. Baron's basic premise (June 21, p. 902)—to wit, that the standard of culture among medical students (and doctors) is distressingly low—there can be no criticism. Of Dr. Baron's recommendations for improvement we say unblushingly they are not Good-enough. Culture is an attitude of mind. The cultured man is one who, as the result of many influences on his mental development, has learnt an instinctive habit of distinguishing the good, the true, and the beautiful from the bad, the false, and the ugly.

Has Dr. Baron asked himself why, with so little interest displayed by the university authorities, a number of students (including, we presume, Dr. Baron) managed to achieve such an outlook on life as he himself deems desirable? By the time the age of medical studentship is reached the seed is already sown. The opportunities for intellectual advancement are available for those who have the interest to seek them out, and if the demand were greater the university concerned would be forced to provide greater facilities. At the moment these are inadequate only in the sense that one feels a larger number of students should be making use of them.

Let Dr. Baron realize that the foundations of a cultured mind are laid much earlier than the time of the anatomy course. Let him recognize that the ability to discourse on existentialism is no more the mark of a cultured intellect than the accurate knowledge of the course and relations of the greater superficial petrosal nerve is the *sine qua non* of a general practitioner. His

plea should be for better schools and broader education brighter architecture and more opportunities for the mass of people to spend their leisure time in more beautiful buildings pursuing more intellectual hobbies than are normally found in the picture- or public-house.

We medicos are not a race apart. We are admittedly a uncouth lot, but like Garson Kanin's millionaire junkman we are "more couth" than the next man—on the average. "The great happiness of life is to be neither better nor worse than the general run of those you meet with." Dr. Baron wisely seeks to raise us all to his own high level, but does he consort only with doctors? And then to seek success by compulsion he will have us all crying with Faust:—

"Zounds, an I were at the strappado or all the racks in the world I would not on compulsion."

London, S.W.16.

POINTS FROM LETTERS

Physical Therapy of Mental Disorder

Dr. D. W. ABSE (Abergavenny) writes: Although the spirit in which Dr. Winnicott (May 17, p. 688) proceeds to deal with the subject is scientific, his argument is marred by the polemical use of analysis. After all, in psychotherapy the unconscious phantasies of the patient are engaged and the therapist assumes the magic mantle of Elijah no less than in physical treatment. Modern commerce is derived from systems of barter, and these replaced themselves by the unfolding of civilization. The modern physician has resulted from the magician's progress, as far as this has reached. To my mind the important aspect of the matter is that the physician should be conscious of the role he is assuming *vis-à-vis* the patient so that he may be able to heal more effectively. Nowhere is this more important than in shock therapy, and it is one reason (among others equally important) why the conception of "psychological shock" needs to be developed. It is to be remembered that there are those who regard the psychological factors which emerge during convulsion therapy as responsible for the changes wrought in the patient. This is only to say that these "factors" can be appreciated on a psychological plane. It is unlikely that they can be appreciated in terms of physiology any more than the onset and development of the mental disorders to which shock methods are habitually applied. . . . Shock methods of treatment are unpleasant for the patient, as anyone capable of making adequate psychological contact with the patient has to allow. They can sometimes drive the patient deeper into his psychosis, just as they can sometimes cause a remarkable emergence and reality-adjustment. It is a further complication that faulty judgments in regard to a patient's response to treatment easily arise. . . .

Choice of Specialist

Dr. G. C. PETHER (Colchester) writes: Dr. Eustace Shipman (June 14, p. 866) has touched on a matter which can be elaborated and is of fundamental importance. I think it will be admitted that the doctor-patient relationship as it now exists is able to give the patient, whose interests are paramount, a fair deal. This is at least true in private practice. If a patient or his relatives wish for another opinion they can get it. . . . Some years ago, when in a subordinate capacity in a hospital, my opinion was overridden because the superintendent considered that a specialist, who only saw the patient at intervals, could judge better than I. As a result of this an unnecessary operation was performed and the patient died. I do not suggest that in the Services this occurred more or less often than in civil life; yet in theory the colonel knew more than the major and the major more than the captain. . . . Where will the patient stand in a National Health Service? The doctor in his area will presumably be there as a result of "negative direction." The specialists from whom other opinions can be obtained, as also other G.P.s, will also be there by some similar process. Will the patient be able to choose a second opinion? . . .

Pruritus Ani as an Allergic Condition

Dr. E. M. FRAENKEL (London, W.) writes: I can confirm Dr. G. L. Davies's remarks (June 28, p. 950) to be correct in some cases of anal irritation in allergic patients, in whom it started when they used medicated toilet paper and stopped after discontinuing to do so. In my case of pruritus ani (June 7, p. 823), however, the toilet paper cannot be blamed, as the patient had used cotton-wool only for a long time due to the intensely painful irritation.

Obituary

WILLIAM GOUGH, F.R.C.S., F.R.C.O.G.

William Gough, formerly professor of gynaecology at Leeds University, died on June 29 at the age of 71. He was born in Leeds in 1876, and received his professional training in the Leeds school of medicine, where he was awarded the William Hey medal as the most distinguished student of his year. He took the London B.Sc. in 1895 and the M.B., B.S. in 1900. At the intermediate M.B. examination he won the gold medal in physiology and histology. In 1909 he became F.R.C.S., and on the establishment of the College of Obstetricians and Gynaecologists he was elected a foundation fellow.

After qualifying, he was Mayo Robson's house-surgeon, and acted for a period as private assistant to Lord Moynihan. He had to wait some time before an honorary hospital appointment became available, and in the meantime he engaged in general practice and also directed a laboratory of clinical pathology. He used to produce excellent histological preparations with the most primitive equipment and in an incredibly short time. He always maintained that these preliminary activities formed a most valuable foundation for his later special work. In 1909 William Gough was appointed to the staffs of the Leeds Maternity Hospital and the Leeds Hospital for Women. He became a lecturer in the University of Leeds and held the chair of gynaecology from 1929 to 1936. He gave much unassuming and painstaking service to the Royal College of Obstetricians and Gynaecologists as a member of the council and as vice-president. He was a loyal and enthusiastic member of the North of England Obstetrical and Gynaecological Society, and of the Gynaecological Visiting Society. He spoke little, and wrote less, so he was little known outside the circle of his immediate colleagues and pupils. Here, however, his influence was deeply felt, and it was invariably characterized by decency and generosity.

He readily gained the trust and confidence of his patients, for they at once recognized, and rightly so, that in his hands they would receive the best possible treatment. As an operator he was ambidextrous, using the scalpel with either hand but the left for preference. There was nothing spectacular about his methods. He did not give the impression of being a "brilliant" operator, but every operation he performed seemed to be done simply and swiftly. This speed was not gained by the sacrifice of any essential detail of technique.

His many activities in hospital work, teaching, and an extensive private practice were sufficient at times to strain even his exceptional capacity for work, but he was never flurried, never worried, and never lost his temper. His family life was singularly happy. The tragic death of his elder son, a young man of great promise, must have been a terrible blow to him, but it was borne with wonderful fortitude. He is survived by a widow, one son, and four daughters.—A.G.

CHARLES PHILIP BRENTNALL, M.C., M.B., F.R.C.O.G.

Charles Philip Brentnall died in Manchester on June 26 at the age of 56. Son of the Rev. Edward Brentnall, he received his early education at St. Paul's School, London, and the Manchester Grammar School, and then, having gained the Dreschfeld Scholarship, proceeded to Manchester University to study medicine. When he was in his second year his father moved to a living in West Lancashire, so Brentnall transferred to Liverpool University. There he had an unusually brilliant career, gaining distinction in the M.B. examinations in anatomy, pharmacology, and pathology, and also winning the Gee Prize.

He qualified in 1915 and, after holding the post of house-surgeon to the Liverpool Northern Hospital, joined the R.A.M.C. He served in the field in Gallipoli, Palestine, and France, rose to the rank of major, and was awarded the Military Cross. After the war he returned for a time to work in Liverpool and was then appointed as a resident to the hospital which he served for the rest of his life—St. Mary's, Manchester. At St. Mary's, he was successively house-surgeon, resident obstetric officer, resident surgical officer, and registrar, and he was elected to the honorary staff in 1923.

Brentnall's work as a gynaecologist was typical of the man. His approach to any problem was a quiet one, and his methods were gentle. In consequence his surgical results were outstandingly good, and his technique served as a model for his juniors. As was only to be expected, he built up a large consulting practice, and his services were in demand over a wide area. His appointments outside Manchester included those of honorary obstetrician to the Stretford Memorial Hospital and honorary consulting gynaecologist to Warrington Infirmary. A foundation member of the College of Obstetricians and Gynaecologists, he served on the council for six years, being raised to the fellowship in 1938. He was also a member of the Gynaecological Club.

Brentnall's contributions to gynaecological literature were made largely in the form of communications to the North of England Obstetrical Society, of which he was a fellow. At its meetings he could always be counted upon to add something of interest to a debate or to give a word of encouragement to a junior member. It was indeed tragic that shortly after his election as president he should be stricken by the illness from which he eventually died.

In his private life Brentnall was singularly fortunate, and he was never so happy as when, in his own home, he could enjoy the companionship of his family and friends. He leaves a widow, a daughter, and a son who is studying medicine.

Medico-Legal

DESCRIPTION OF A CHEMIST

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A recent case concerning a chemist turned on the description of premises where no qualified chemist is in charge. Under the Pharmacy and Poisons Act, 1933, it is unlawful for a person to use a description in connexion with the business reasonably calculated to suggest that he or anyone employed in the business possesses any qualification with respect to the selling, dispensing, or compounding of drugs or poisons other than the qualification which he in fact possesses. A registered qualified chemist and druggist named Mr. Spink owned eleven chemists' shops. Qualified assistants were in control at ten of these, but none was available for the eleventh. This shop, like the others, was carried on under the name of "Spink's, the Chemist," but it had a placard in the window stating that owing to war circumstances there was no qualified assistant in charge of the shop and medicines could not be dispensed. An inspector of the Pharmaceutical Society bought glycerin and rose-water in a bottle labelled "Spink's, Chemist," and the society prosecuted Mr. Spink for a breach of the Act. The justices dismissed the case, and the Society appealed.¹

The High Court upheld the justices. Lord Goddard, Chief Justice, refused to read the Act as though it said, not "he or anyone employed in the business" but "he or any person in control of premises where the business is carried on." He also pointed out that, whereas the Act says that the word "pharmacy" in a description is to be deemed to be reasonably calculated to suggest that the owner of the business and the person in control are registered pharmacists, yet there is no such prohibition of the use of the word "chemist." His Lordship thought that the title complained of meant only "This is a shop belonging to Mr. Spink, who is a chemist." The word "chemist" over the shop, taken together with the placard, was not reasonably calculated to suggest that the person in charge had a qualification which in fact he had not. Mr. Justice Atkinson and Mr. Justice Oliver agreed.

¹ *Dentley v. Spink* (1947) 1 All E.R. 835.

The Minister of Labour and National Service has formulated new Regulations (H.M.S.O., price 6d.) in the light of the report of the Dust-Tile Committee, published in 1943, and of recommendations made by the National Council of the Pottery Industry in 1945. Conferences for examining the Regulations will probably be held in the autumn.

Medical Notes in Parliament

FOOD AND HEALTH

On July 1, on the estimates for the Ministry of Food, Mr. J. S. C. REID opened the debate with a reference to the statement of the previous day by Mr. Dalton indicating coming reductions in imports. Mr. Reid said he had yet to see any survey which showed that the majority of the people of this country who did not have access to canteens and restaurants consumed more than 2,400 calories a day. Calories told only half the story. Otherwise bread and water would be a good diet. Weight for weight there were more calories in bread than in stewed steak and twice as many calories in sausages as there were in chicken. Weight for weight stout had more calories than smoked herring.

Mr. STRACHEY said the average number of calories consumed per head per day at the moment by the people of this country was between 2,880 and 2,890. The figure of 2,325 which had been adduced by Col. Walter Elliot was what the national figure would be if no one in the country consumed any food in catering establishments and if some types of rationed foods under the personal points scheme were disregarded. Using this completely false figure Col. Elliot alleged that the nation was gravely undernourished, and his less cautious supporters alleged that it was starving to death. The figure of 2,325 came from the National Food Survey for the first quarter of 1947. The comparable figure in 1941 was 2,360, in 1942 it was 2,253, and in 1943 it was 2,315. If the nation was slowly starving to-day it was starving a little more quickly while Lord Woolton was in office. He did not suggest that 2,890 was a highly satisfactory level, but it was a good level in comparison with previous periods. The Government aimed to put the whole population of the country upon a higher level. To-day the difference of intake among individuals was largely according to need instead of according to class. There was comparatively little difference in the intake of the different wage groups.

Mr. BAKER WHITE pointed out that 84% of the meals eaten in this country were eaten in the homes and only 13% in catering establishments. National supplies of fruits including tomatoes and pulses were more than 20% below pre-war levels, but supplies of vegetables were about 10% above pre-war, and potato supplies had increased to about 64% above the pre-war level.

Mr. MICHAEL FOOT said tests by experts in this and other countries proved that the infantile mortality rate and the maternal mortality rate gave a proper indication of nutritional standards. In England during 1936 the infantile mortality rate was 62 per thousand. To-day, under Mr. Strachey, it was 46 per thousand and still going down. The same was true of the maternal mortality rate, which was the lowest on record. By comparison with pre-war days the height and strength of children in this country were greater. In Plymouth children born and brought up in the "blitz" were healthier, stronger, and better than any children ever born in this country before.

Mr. WILFRID ROBERTS said he had obtained the article by Dr. Bicknell entitled "Dying England." It was first-class political propaganda with opinions on statistics, political economy, and agriculture, on the last of which Dr. Bicknell quoted what seemed to him, Mr. Roberts, to be quacks.

Mrs. AYRTON-GOULD said Dr. Bicknell knew nothing about the unemployed and nothing about food. Before the war half the population of Britain spent from 4s. to 8s. a week on food and 50% of the population had an average of 2½ oz. of butter a week, whereas the nation was now getting 3 oz. per week per head and everyone was able to buy it. The same 50% had 3 oz. of margarine a week, which was the same as the present ration. The 1s. 2d. worth of meat which the nation now bought weekly was far above the amount the average person could afford to buy before the war. The consumption of milk to-day was 50% more than before the war. The excess went in the welfare services and to the people who needed it most. All ordinary housewives were able to buy 2½ pints a week, which, according to Sir John Orr, was the average milk consumption before the war. That was why the health of the population was much improved. Deaths from tuberculosis in England and Wales in 1935 numbered 29,201. The population had increased in the subsequent ten years, but the figure for 1945 was 23,955. People who talked about the nation being ill-fed talked absolute nonsense. The nation was being well fed, though monotonously fed.

More Milk

Lady GRANT said the nation was consuming 30% more milk at the expense of butter and cheese and processed milk. She

quoted figures from a review in 1937 by Sir William Crawford. They concerned the group with incomes below 48s. per week. In 1937 these people consumed on an average 26.8 oz. of meat per week while the nation now consumed 16.2 oz. per head. They then consumed 3.6 oz. of bacon whereas the ration was now 2 oz. In fats they consumed in 1937 10.2 oz., while the ration was now 7 oz. Since 1945 there had been cuts in several vital rations while more goods had been based on points. The nation was consuming more starchy products, and who would say these products were a good substitute for fats or proteins? The result of the lack of quality in the diet was having a great effect on the people's will to work and brought chronic fatigue with many minor ailments which were not notifiable, such as general debility and gastritis.

Dr. HADEN GUEST asked how the Government was going to fortify the health of the people and give them extra resistance in the event of the next winter being as bad as the last. The difficulties at present were not due to food, which was extremely good, but to the fact that all were suffering from the results of war strain. He thought there should be an extension of food for certain classes of heavy workers, including miners. Much could be done by ensuring that all the children entitled to priority milk actually received it. He believed that they did so in the towns. He hoped that the priority supply of eggs to children up to the age of 2 years could be extended to the age of 5, 6, or 7. Extra proteins for heavy workers, particularly miners, would help. He suggested that the Government should secure an increased supply of rice from Siam at an early date and said it was important that strong action should be taken to prevent the destruction by the Japanese of the world's supply of whales. Although he did not now practise, he recognized the enormous improvement in health at present compared with the condition of things after the 1914-18 war. The condition of the children on the continent of Europe in 1919 was appalling. One reason for considering that this country and the world were in a better state than at the end of the 1914-18 war was that there had not been anywhere in the world any large-scale post-war epidemic. With the exception of the U.S.A. and Canada every single country had a lower standard of food than Britain had at present and the general condition of the people was not as good as it was here. That was true everywhere, in Europe and in the East. Child health statistics, maternal health statistics, and the general health and vigour of the country showed that we were better fed now than in the inter-war period.

Dr. BARNET STROSS said that the world to-day was short of one million tons of grain and had 10% less sugar than before the war. Europe was short of meat by 40%, and the rest of the world by 10%. The world population had increased since 1938 by 5 to 10%. If the diminution in British meat supplies was 9%, then we had not done badly. They knew that between 1913 and 1934 the health of the people improved dramatically, in association with an increase in consumption of leafy green vegetables and fruit by 75% and of dairy produce by 50%. Expectation of life increased by 7 years; the death rate of infants dropped from 100 to 57; the tuberculosis rate was halved; and the children became taller, healthier, and stronger. The change continued throughout the war and to-day. The reason was that everyone had been compelled to eat less animal protein, and therefore ate much more summer fruit and leafy green vegetables. They consumed more liquid milk, and the quality of the fats was better; the vitaminization of margarine gave great protection. The better quality of bread and the fact that the nation ate more potatoes, which contained ascorbic acid, meant that the diet was healthier even though it was not fuller and was more monotonous.

Fewer Calories

Col. ELLIOT said everyone in the House feared that the standard of living in this country was in jeopardy. Prof. Marrack had said it was unfortunate that Government spokesmen continued to claim that the average calories per head per day were in the neighbourhood of 2,900. He declared that surveys of the Ministry of Food made on representative families showed that the average per head ranged from 2,300 to 2,400. Meals taken outside could not raise the total to more than 2,650. Drs. Bransby and Magee, of the Ministry of Health (B.M.J., April 19, p. 525), pointed out that classes such as farm workers, quarrymen, and lumbermen who could not get access to canteens would require, in addition to their special allowances, to eat up to 14 lb. of potatoes per week. Miners not in receipt of canteen facilities would require to eat 10½ lb. of potatoes per week or else to draw on the family pool by consuming other people's rations. The document "Food Consumption Levels" showed that about 2,800 calories per head was necessary to have an intake actually eaten of 2,500 calories per day. Yet the document further said that at

,700 calories the diet would be too low. The nation was living on a very narrow margin. Nevertheless it was true that in the main the health records had been excellent and the general condition of the country had greatly improved. The energy output figures made a different picture. They seemed to indicate that at present full employment was not practicable in the condition of nutrition of the people and that any reduction in the intake would lead the country into great danger. Tuberculosis figures did not bear the favourable interpretation put upon them. The death rate per million in England and Wales since 1939 was in no case as low as before the war and the notifications had gone up from 37,000 in 1938 to 42,000 in 1945. In Scotland the figures of deaths per million from tuberculosis were 520 in 1938 and 640 in 1946. Notifications in Scotland were 4,790 in 1938 and 7,500 in 1946.

Dr. STEPHEN TAYLOR pointed out that mass radiology had been introduced during the war with an increase in the notifications.

Col. ELLIOT said the nation was working on a too narrow surplus of energy intake over energy output. Its general health was good, but it found itself in difficulty in putting out a long and sustained effort such as the Government called for. Many sources of our food were in peril. The yield of fish was beginning to fall off, as happened after the first world war.

Dr. EDITH SUMMERSKILL said that the nation was adequately fed although the present diet left much to be desired in variety. She would not go into the question of calories except to quote Sir Wilson Jameson, who, in the Ministry of Health Report for the year ended March 31, 1946, which had been published seven weeks ago, said that as far as clinical surveys of the state of nutrition of groups of the population and the heights and weights of children were reliable the nutrition of the population generally remained good. Children in 1945 were of better physique than corresponding children in 1940 or before the war. She had just received figures for Scotland which showed that in 1938 the infant mortality in that country was 70 per 1,000, in 1944 65 per 1,000, and in 1946 53.8. The figures for neonatal mortality were 35 in 1938, 32.8 in 1944, and 29.2 in 1946. The maternal death rate figures were 4.9 in 1938, 3 in 1944, and 2.2 in 1946. In 1938 deaths from tuberculosis in Scotland were 69 per 100,000 population, in 1944 they were 82, and in 1946 they were 79.

Col. ELLIOT said he had quoted figures for deaths from respiratory tuberculosis.

Dr. SUMMERSKILL said pulmonary and non-pulmonary tuberculosis should be feared equally.

A motion to reduce the estimate was defeated by 278 to 113.

Medical Members of Executive Councils

Mr. HASTINGS, on June 26, asked the Minister of Health whether, in selecting representatives of the medical profession for the local executive councils under the new Health Act, he asked for nominations from the medical committees in the various areas, and whether he knew that in not a few of these areas medical committees were elected in 1938 and there had been no election since.

Mr. BEVAN replied that appointments of medical members to Executive Councils were made by the Local Medical Committees and not by the Minister. He knew that in most areas there had not been elections for Panel Committees since 1939. Therefore his recognition of Local Medical Committees for the new Service had been provisional.

Northern Ireland Bill

When the House of Commons on June 27 was in committee on the Northern Ireland Bill, debate arose on Clause 4, which empowers the Northern Ireland Government to provide health services. Mr. MULVEY moved a proviso that wherever the associations of a voluntary hospital linked it with a religious denomination, all attention should be paid to preserve the character and associations of the hospital in the general management and in making appointments to the board of management. The proposed amendment further provided that all endowments of such hospitals should remain their property. Mr. Mulvey pointed to a similar provision in the National Health Service (Scotland) Act, Section 60. Mr. GAGE said that a hospital in Belfast which derived strength from its religious links was one of the best hospitals in that city.

Mr. EDE said he understood that the Northern Ireland Government decided to follow Section 61 of the English Act, which incorporated the principle of the first proviso. Parliament had refused to insert the principle of the second proviso in either the English or the Scottish Bill.

Mr. Mulvey withdrew his amendment.

The Report stage was concluded and the Bill was read a third time.

Typhoid at Bombay

Mr. PHILIP NOEL-BAKER stated on July 2 that in 1946 there were 32 cases of typhoid at Worli camp, Bombay; this year there had been 11 cases. In 1946 one man died; on grounds of conscience he had refused inoculation. As soon as the water supply was found to be infected all drinking water was chlorinated in mobile tanks. New mains were installed last December. Analysis had shown that the water was now free from all infection, but as an additional precaution the mobile tanks were still in use.

Voluntary Funds

Asked on July 3 by Mr. SPARKES to state his attitude toward the continuance of such voluntary efforts as fêtes, bazaars, and sales of work for the benefit of particular hospitals, Mr. BEVAN said the governing bodies would have power to receive and hold voluntary funds from any source independently. No charges could be made on patients for any part of the service except those specifically mentioned in the Act or Regulations. Each of the hospitals could raise funds for additional purposes such as welfare. During the Committee and Report stages of the Bill he had made it clear that hospital committees could themselves organize voluntary funds under the new arrangement. These funds would in no way diminish the revenue provided by the State.

Signing of Death Certificates

Mr. SPARKES asked on July 3 what precautions were taken to secure that the cause of death certified upon a death certificate was correct; and, in view of the evidence at the recent coroner's trial at Southport, what steps Mr. Bevan proposed to take to ensure that death should not be certified from wrong or false causes. Wing-Commander HULBERT inquired if Mr. Bevan was aware that the law now permitted medical practitioners to issue death certificates in respect of near relatives, and if he proposed to introduce legislation to amend this practice.

Answering both questions, Mr. BEVAN said that the position under the Births and Deaths Registration Acts and Regulations was that a registered medical practitioner who was otherwise competent in the circumstances of the particular case to give a certificate of the cause of death was not precluded from doing so by reason of relationship to the deceased. It was not open to the registrar of births and deaths to reject a certificate on that ground. The duties of the registrar included the duty to report to the coroner, before registration, deaths in specified categories, including any which he had reason to believe to be unnatural or accidental, or attended by suspicious circumstances, or the cause of which appeared to be unknown. Mr. Bevan added that at present he did not contemplate amending legislation on any of these matters. He had no comment to make on the circumstances of a recent case at Southport and would not derive a general conclusion from that particular instance.

Mr. HECTOR HUGHES suggested that death certificates should be countersigned by an independent practitioner. Mr. Bevan repeated that he did not contemplate any amendment of the law at present.

Nurses.—On Jan. 1, 1946, the number of State registered and enrolled assistant nurses in Scotland was 17,767. On May 31, 1947, the number was 20,858. The numbers of women who became student nurses in Scottish hospitals during 1945, 1946, and the first five months of 1947 are estimated as 2,500, 3,200, and 1,300.

The Deaf Blind.—All blind-welfare authorities provide for the visitation and instruction of deaf-blind persons by home teachers.

The Services

The Air Force Cross has been awarded to Acting Wing-Commander R. Maycock, R.A.F.

The following appointments and mentions in dispatches in recognition of gallant and distinguished services in the Netherlands East Indies prior to Nov. 30, 1946, are announced:

O.B.E. (Military Division): Miss Perin K. Mullaferoze, F.R.C.S., Lieut.-Col. (temporary); Lieut.-Col. (temporary) S. L. Rikbye, M.B.E., I.M.S.

M.B.E. (Military Division): Captain (temporary) Lal Chand, I.A.M.C.

Mentions in Dispatches: Brigadier (temporary) G. S. Douglas, late R.A.M.C.; Lieut.-Cols. (temporary) B. Blewitt and V. J. Keating, R.A.M.C.; Capt. H. Foster, R.A.M.C.; Lieut.-Col. (temporary) G. Ahmed, I.A.M.C.; Majors (temporary) K. R. Rama Rao and M. R. K. Siddique, I.A.M.C.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 21.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Smallpox

At Barnsley, after an interval of four weeks, the sixteenth case was detected and removed to hospital on June 30. The diagnosis has been confirmed by the recovery of variola virus on egg culture. The patient is a woman aged 62, vaccinated in infancy and during the 1914-18 war. She is suffering from a modified attack which began on June 24. A discrete rash appeared on June 28. The source of infection is at present undetermined.

At Bilston a schoolboy aged 10 was removed on July 2 on suspicion. A rash had appeared on the previous day. He had been vaccinated on June 23. Confirmation of diagnosis is not yet available.

Poliomyelitis

Notifications for the week ending June 28 show a further increase to 56, compared with 44 in the previous week and 8 in the corresponding week of 1946. The disease is widely scattered over the country, some three dozen sanitary districts being involved.

Polio-encephalitis

Polio-encephalitis notifications have also jumped to 11 from an average of 2 to 3 a week. It is not yet known whether this rise is merely a reflection of the incidence of poliomyelitis or whether there is in fact a prevalence of encephalomyelitis and encephalomeningitis distinguishable from anterior poliomyelitis and resembling the series of cases described by Jennings (*Lancet*, 1947, 1, 471). An increase in cerebrospinal fever notifications to 57 may have some significance in this connexion.

Notification of Puerperal Fever to Cease in London

The London County Council is proposing to promote legislation next session to provide that puerperal fever shall cease to be a notifiable infectious disease and a dangerous infectious disease for the purpose of the Public Health (London) Act, 1936. In the provinces puerperal fever was notifiable up to September, 1937, under the Infectious Diseases (Notification) Acts, but these were repealed by the Public Health Act, 1936, and the disease was omitted from the list of notifiable diseases in section 343 of that Act. Puerperal pyrexia is notifiable in London under Regulations issued in 1926 and 1928 by the Ministry of Health, and in the provinces under Regulations issued in 1939, which, except in London, replaced the earlier ones. The Regulations are difficult to understand, and the statistics obtained on the present basis have been found valueless. As the separate notification of puerperal fever in London is not found to serve any useful purpose, it is considered that the Public Health (London) Act should be amended by the removal of puerperal fever from the list of notifiable infectious diseases and also from the list of dangerous infectious diseases. This will leave puerperal pyrexia to be dealt with solely by Regulations of the Minister under the Public Health Act, 1936, and by orders of the L.C.C. and the sanitary authorities under the London Act.

Discussion of Table

In England and Wales there was an increased incidence of whooping-cough 45, scarlet fever 37, diphtheria 25, while a decrease was reported for measles 164 and acute pneumonia 52.

The returns for scarlet fever and whooping-cough for local areas showed only small variations from the total notifications of the preceding week. The only large fluctuation in the local incidence of diphtheria was an increase of 25 in Lancashire, these cases being dispersed throughout the county and not due to a localized outbreak. The downward trend in the notifications of measles ceased in several counties, the largest increases being London 122, Glamorganshire 107, Sussex 104; the only large decreases were Yorkshire West Riding 432 and Surrey 130.

Although the total number of notifications of dysentery were practically unchanged, the cases were more widely dispersed. The 47 cases were notified in 21 counties—compared with 48 notifications from 14 counties in the preceding week. All the cases of smallpox notified were from Bilston U.D., Staffs. There were 44 cases of poliomyelitis—an increase of 13 on the high level of the preceding week—involving 21 counties. The only area with a number of cases was Barrow-in-Furness C.B., Lancs, where 5 cases were notified.

In Scotland there was an increase in the notifications of acute primary pneumonia 60, and scarlet fever 24, while decreases were recorded for measles 34, whooping-cough 21, dysentery 20, and cerebrospinal fever 8.

In Northern Ireland the chief features of the returns were increased incidence of measles 10, scarlet fever 5, and diphtheria 4. Six cases of typhoid fever have been notified in Belfast up to June 26.

THE OVERACTIVE THYROID WITH METHYL THIOURACIL (‘GENATOSAN’)

Evidence is now accumulating that Methyl Thiouracil (‘Genatosan’) will control the thyrotoxic state more satisfactorily than will Thiouracil. Where, because of tracheal obstruction, or for cosmetic reasons, subtotal thyroidectomy is necessary, Methyl Thiouracil (‘Genatosan’) may be used in conjunction with iodine to prepare the patient for surgery.

Something entirely NEW in ELASTIC STOCKINGS

These points make Lastonet the ideal Surgical Stocking:—

- ★ Made from light - weight, washable elastic net, they combine minimum weight with full support.
- ★ Net construction allows the air to circulate freely over the skin, making the stocking cool and comfortable to wear.
- ★ Every stocking is made-to-measure in full or knee-length. Measurement forms are obtainable from leading chemists or, in case of difficulty, direct from the makers.
- ★ Lastonet is invisible under the normal stocking.

Despite the very heavy demand for Lastonet, we shall continue to give the best possible delivery

“MOIST HEAT”

FOR

PAIN, SWELLING, SORENESS

In the treatment of boils or other localized infections where “Moist Heat” is indicated, the “Moist Heat” of ANTIPHLOGISTINE helps relieve pain, swelling and soreness.

Applied comfortably hot, ANTIPHLOGISTINE supplies “Moist Heat” for several hours. ANTIPHLOGISTINE may be used with chemotherapy.

The “Moist Heat” of ANTIPHLOGISTINE is also effective in relieving the pain and swelling of a sprain, bruise, or similar injury or condition.

invented by a Doctor . . .

TAMPAX, first introduced in 1934, was the direct adaptation by a practising Doctor of the principle of the surgical tampon to the absorption of the menstrual flow. As such, it received the approval of the medical profession, not only for its alleviation of mental stress and physical discomfort but for its hygiene and absolute safety—ensured by the Tampax patent stitching process which

positively prevents disintegration. Today that approval is world-wide. Tampax is recognised as both the pioneer and the best form of sanitary protection worn internally. If you are not receiving copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to: Medical Inquiries, Tampax Ltd., 110 Jermyn St., London, S.W.1.

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenial aperture would cause difficulty in insertion and withdrawal.

PENICILLIN OIL - WAX SUSPENSION

In general practice intramuscular injection of an oil-wax suspension constitutes the most convenient method for systemic administration of penicillin.

The comparatively low viscosity of Penicillin Oil-wax Suspension (Ethyl Oleate) B.D.H. facilitates administration without preliminary warming and an unduly wide bore needle is not required.

UNIVERSITY OF GLASGOW

ames Norman Davidson, M.D., D.Sc., professor of biochemistry a the University of London, has been appointed to the Gardiner Chair of Physiological Chemistry in the University of Glasgow, in succession to Prof. G. M. Wishart.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ELECTION TO THE COUNCIL

On July 3 Mr. R. J. McNeill Love was re-elected and Mr. A. Lawrence Abel and Mr. J. B. Oldham were elected members of the Council of the College. In addition Sir James Walton received the requisite number of votes but is prevented by the terms of the 1947 Charter from taking his seat on the Council as he has already served for sixteen years. There will, therefore, be a vacancy until he next election. The Fellows elected were:

	Votes
Robert John McNeill Love (Royal Northern) ..	839
Sir James Walton (London) ..	835
Arthur Lawrence Abel (Princess Beatrice) ..	637
James Bagot Oldham (Royal Liverpool United) ..	629

The following were the other candidates:

Arthur Dickson Wright (St. Mary's) ..	609
Hubert Wallace Symons (General Infirmary at Leeds) ..	557
Harold Clifford Edwards (King's College) ..	478
Louis Carnac Rivett (Middlesex) ..	356
Marriott Fawcner Nicholls (St. George's) ..	277

In all 1,563 Fellows voted: in addition six votes were found to be invalid.

Medical News

The Association of Surgeons

The Association of Surgeons of Great Britain and Ireland held its annual dinner in the Hall of Christ Church, Oxford, on July 3 with the President, Sir Hugh Cairns, in the chair. Prof. Geoffrey Jefferson, F.R.S., proposing the toast of the Association, quoted Southey and Spratt as witnesses against the volubility of those who make public utterances. In referring appreciatively to some of the early members of the Association of Surgeons, he said that a man who was incapable of worshipping heroes was lacking in one of the great qualities of the human spirit. Those who with Moynihan had started the Travelling Surgical Club had as one of their aims the breaking down of the jealousy unfortunately characteristic of surgeons in some other countries. Prof. Jefferson coupled the toast with the name of the President. In response Sir Hugh Cairns gratefully acknowledged the hard work done by the Hon. Secretary of the Association, Mr. H. W. S. Wright, and its Hon. Treasurer, Mr. R. M. Handfield-Jones. He paid a tribute to the memory of two absent friends—the late Mr. Tudor Edwards, who is now commemorated in the Tudor Edwards Travelling Fellowships in Thoracic Surgery; and the late Hugh Whitelocke. Sir Hugh gave a message of welcome to the Association from Dr. Elliot Cutler. He spent some time in discussing the evolution of the Nuffield Clinical School of Medicine in Oxford. He pleaded that they should not aim at producing a standard type of surgical professor, and that they should avoid excessive regimentation and standardization in their schools. Sir Alfred Webb-Johnson, in a characteristically humorous speech, proposed the health of the guests, welcoming in particular those from other countries: Prof. René Leriche, Prof. H. E. F. Albert, Prof. R. Danis, Prof. J. de Faumestruat, Dr. Lortat-Jacob, Prof. L. Mayer, Prof. J. Morelle, Dr. L. Bazy, Prof. W. Noordenbos, and Dr. W. K. Livingston. He thanked those whom he described as their hosts and guests: Sir Richard Livingstone, Vice-Chancellor of Oxford University; and the Dean of Christ Church. It was fitting, he said, that Sir Hugh Cairns, as a Rhodes scholar, should hold the first Commonwealth Travelling Fellowship. Sir Alfred paid a handsome tribute to their benefactor, Lord Nuffield, whom Sir Hugh Cairns had described earlier as "the Cowley father of modern medicine." Responses were made on behalf of the guests by Sir Richard Livingstone and by Prof. René Leriche.

More Nurses

Presenting medals and certificates at the Middlesex County nurses' examination on June 20, the Minister of Health said that more girls were entering the nursing profession now than before the war—about 14,000 annually compared with something over 11,000. Under the National Health Service two developments that would help to provide the best possible training for nurses would be wider facilities made available by the regionalization of hospitals and the fact that the desirability of full student status for the nurse in training was becoming increasingly recognized.

Dental Surgery at Glasgow

Sir Hector Hetberington, Principal of Glasgow University, announced at the annual prize-giving ceremony on June 27 at the Glasgow Dental Hospital and School that the University had taken over the control of dental education in Glasgow and would institute a degree in dental surgery. The University will select next year's entry of students to the Dental School.

Free Supplies for Day Nurseries

Every child attending a day nursery both in the morning and in the afternoon is now allowed two-thirds of a pint of liquid milk (or national dried milk when necessary) free of charge. Free cod-liver oil (6 oz. for 12 weeks) and a bottle of orange-juice (price 5d.) every 4 weeks is also allowed. Day nurseries should register for benefit under the Welfare Foods Scheme as set out on Form WF/DN.15, obtainable from the Ministry of Food. A day nursery not administered by a welfare authority should submit this form to the medical officer of health for certification that it is entitled to receive benefit. The local food office will then make the necessary arrangements. The milk benefit is applied for on Form WF/DN.4, which is renewable at quarterly intervals and obtainable from local food offices. The source and quality of the liquid milk must be approved by the medical officer of health.

Called to the Bar

Jeffrey Murray Robertson, M.B., B.S. (Inner Temple), and Thomas Kemp Homer, M.B., Ch.B. (Gray's Inn), were called to the Bar on June 18.

Wills

Dr. John Wallace, of Weston-super-Mare, who died on Feb. 13, aged 90, left £32,846. Mr. Christopher Tredwell Holford, of Tiverton, Devon, formerly senior surgeon of Burton-on-Trent Infirmary, left £34,492. Dr. George Montgomery Drury, of Cheadle Heath, Stockport, left £2,372. Mr. Walter Graham Stewart, of Ware, Herts, left £26,548. Sir Richard Robert Cruise, surgeon oculist to King George V and to Queen Mary, owner of the famous steeplechaser War Gratitude, left £40,215. Sir Walter Langdon-Brown, of Cambridge, left £23,630. Mrs. Catherine Mabel Edgerley, of Menston, Yorks, one of the first women to qualify and an authority on the Brontes, left £29,533.

COMING EVENTS

Athletics

The City and Hospitals Charity Athletic Contest for the *Financial Times* Challenge Shield is being held at the London University Sports Ground, Molesbury Park, Surrey, on July 12. The first event is at 3 p.m. Admission at the gate is 1s. 6d.

Labour Saving Hospitals

An exhibition of labour-saving devices for use in hospitals will be opened by the Minister of Health on July 14 at 3 p.m. at the Empire Tea Centre, 22, Regent Street, London, S.W.1. It has been organized on behalf of the Ministry of Health by the British Electrical Development Association and the British Gas Council. Exhibits will include special cleaners and polishers, a bed-pan sterilizer, cooking utensils and ice-cream makers, laundry apparatus, and suggestions for brightening the domestic staff's private rooms. The exhibition is open in the morning only to hospital representatives, and to the public every afternoon from 1-5.30 p.m. It will close on Aug. 2.

The Physiology of Lactation

The Kent Paediatric Society has arranged for Dr. H. Waller to give two addresses on "The Physiology of Lactation and the Causes of Early Failure" at the County Hospital, Farnborough, on Tuesdays, July 15 and 22, at 8 p.m. Hospital paediatric and maternity nurses, midwives, and health visitors are invited to attend the lectures.

Kelynaek Memorial Lecture

Prof. F. L. Golla, F.R.C.P., director of the Burden Neurological Institute, will deliver the inaugural Kelynaek Memorial Lecture on "Alcohol and the Neuroses" before the Society for the Study of Addiction at Westminster Hospital Medical School, Horseferry Road, London, S.W., on Tuesday, July 15, at 4 p.m.

Tuberculosis Conference

The joint annual conference of the Tuberculosis Association and the Tuberculosis Society of Scotland will be held in the Department of Zoology, King's Buildings, West Mains Road, Edinburgh, on July 16, 17, and 19. The programme is as follows: July 16, 2.15 p.m., opening address by the Marchioness of Linlithgow; 2.45 p.m., Dr. H. A. Pattison (New York), "Rehabilitation in the U.S.A."; 4.45 p.m., discussion, to be opened by Mr. T. Holmes Sellers, "Assessment of the Results of Thoracoplasty," followed by a general discussion in which several thoracic surgeons will give brief reviews of their results; 8.15 p.m., annual general meeting of the Tuberculosis Association; 9.15 p.m., Dr. H. P. Tait, "Edinburgh Medical Men at the Time of the Resurrectionists." July 17, 3.30 a.m., Dr. H. Van den Berg (Amsterdam), "The Control of Results in B.C.G. Trials"; 11 a.m., Dr. J. G. Scadding, "The Pneumonias Associated with Epidemic Respiratory Infections"; 2 p.m., Dr. V. Reilly, "The Pathology of Amyloidosis"; 3 p.m., Dr. W. M. Borthwick, "Genito-urinary Tuberculosis"; 4.45 p.m., Prof. V. Monaldi (Naples), "Endoeavitary Aspiration in the Treatment of Pulmonary Tuberculosis"; in the evening there will be a special performance of "The Anatomist" in the Little Theatre. July 19, 9.30 a.m., Mr. Norman Dott, "Skeletal Traction, Surgical Decompression in the Management of Pott's Paraplegia"; 11 a.m., discussion on "The Causes of the Breakdown of Discharged Quiescent Cases," to be opened by Dr. Alex. MacLean and Dr. B. R. Clarke. July 18 will be devoted to recreation, with a golf match at Gullane, an excursion to the Border country, and a garden party in the afternoon; in the evening there will be a joint annual dinner, preceded by a reception at the Grand Lodge of the Freemasons.

Penicillin Treatment of Syphilis

A joint meeting of the Medical Society for the Study of Venereal Diseases and the Section of Experimental Medicine and Therapeutics of the Royal Society of Medicine will be held at 1, Wimpole Street, London, W., on Thursday, July 17, at 5.15 p.m., when a discussion on "The Treatment of Syphilis with Penicillin" will be opened by Dr. Earle Moore (U.S.A.), Dr. G. L. M. McElligott, and Dr. E. M. Lourie.

Modern Anaesthesia

Dr. I. W. Magill has accepted the invitation of the Royal Institute of Public Health and Hygiene (28, Portland Place, London, W.) to be the Bengué Memorial Award Lecturer for 1947. His subject is "A Review of Modern Anaesthesia," and the lecture will be delivered at the institute on Thursday, July 17, at 3 p.m. Admission is free, without ticket. Seats may be reserved upon application to the secretary of the Institute.

APPOINTMENTS

Dr. Vincente Banet and Dr. José Lástra have been appointed president and vice-president respectively of the National Society of Surgery of Cuba.

Mr. J. F. Foster, formerly registrar of the University of Melbourne and secretary of the Australian Vice-Chancellors' Committee, has been appointed secretary of the Universities Bureau of the British Empire, on the retirement of Mr. W. B. Brander.

Dr. P. S. Selwyn-Clarke, C.M.G., M.C., has been appointed Governor and Commander-in-Chief of the Colony of Seychelles.

John Watkins-Pitchford, M.D., has been appointed H.M. Inspector of Factories.

BIRMINGHAM: SELLY OAK HOSPITAL.—*Chief Assistant Surgeons*, A. R. Leah, F.R.C.S., J. R. A. White, F.R.C.S.Ed., G. R. Clarke, F.R.C.S.Ed., *Chief Assistant Physicians*, W. M. Philip, M.B., M.R.C.P., W. P. U. Jackson, M.D. M.R.C.P., I. A. Guest, M.D., M.R.C.P., *Chief Assistant Gynaecologist and Obstetrician*, M. L. Neville, M.B., D.R.C.O.G., *Anaesthetist*, T. H. Hobbs, M.B., D.A., *Resident Assistant Anaesthetist*, J. E. McCutcheon, M.B., Ch.B.

BLACKWOOD, WILLIAM, M.B., F.R.C.S.Ed., Assistant Pathologist, National Hospital, Queen Square, London, W.C.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford, E.—*Honorary Assistant Obstetric Surgeons*, H. H. Fouracre Barnes, F.R.C.S., and B. G. Spinks, F.R.C.S.Ed.

REES, HARLAND, M.Ch., F.R.C.S., Surgeon, St. Peter's Hospital for Stone, Henrietta Street, London, W.C.

SEYMOUR-JONES, ANTHONY, F.R.C.S., D.L.O., Honorary Assistant Surgeon to Ear, Nose, and Throat Department, Portsmouth and Southern Counties Eye and Ear Hospital.

SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W. Tuesday and Thursday, July 15 and 17, 5 p.m. Humphry Davy Rolleston Lectures by Dr. P. C. P. Cloake: Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Thursday, July 17, 6.15 p.m. Charles Tomes Lecture by Prof. J. G. Turner: Movements of Teeth.

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tuesday, July 15, 5.30 p.m.

Section of Experimental Medicine and Therapeutics.—Thursday, July 17, 5 p.m. Annual general meeting: Election of Officers and Council for 1947-8. 5.15 p.m. Joint Meeting with the Medical Society for the Study of Venereal Diseases. Discussion: The Treatment of Syphilis with Penicillin. Openers: Drs. Earle Moore, G. L. M. McElligott, and E. M. Lourie.

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, London, W.—Thursday, July 17, 8 p.m. Twenty-fourth Mackenzie Davidson Memorial Lecture by Dr. John H. Lawrence (University of California): Application of Artificial Radioactivity to Biology and Medicine.

MEDICAL SOCIETY OF LONDON, 11 Chandos Street, W.—Monday, July 14, 8.30 p.m. Mr. F. A. Williamson-Noble, Contact Lenses; Dr. G. B. Dowling, Athlete's Foot; Mr. A. Dickson Wright, Pruritus Ani.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BEALE.—On June 27, 1947, at Bridgwater, to Violet, wife of Dr. J. Hanway Beale, a daughter.

MARRIAGES

BROWN-DANOS.—On June 25, 1947, Arthur Edward Brown, L.R.C.P., M.R.C.S., D.P.H., and Irene Danos, Budapest, Hungary.

EVANS-MORE.—On May 31, 1947, at Ipswich, Gordon M. Hylton Evans, M.R.C.S., L.R.C.P., to Hannah Mary More, S.R.N.

ILLINGWORTH-REDHEAD.—On July 3, 1947, in Newcastle-upon-Tyne, Professor Ronald Illingworth, M.D., F.R.C.P., D.P.H., D.C.H., to Cynthia Mary Redhead, M.B., B.S., M.R.C.P.

LOVETT-HARRY.—On July 5, 1947, at Peterstone-super-Ely, Glamorgan, William Charles Donald Lovett, B.Sc., M.B., B.Ch., B.S., to Frances Mary Harry.

RUTTER-STEVENS.—On July 5, 1947, at Caxton Hall, London, S.W.1, Clarence Rutter, M.R.C.S., L.R.C.P., to Mrs. Mary Stevens.

WALTERS-LARGE.—On June 30, 1947, in London, Geoffrey A. Barot Walters, F.R.C.S.Ed., to Mrs. Daphne Large (née Pullin-Thompson).

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Acute Poliomyelitis

Q.—I am of the opinion that acute anterior poliomyelitis is related to gastro-intestinal infection, and that the main essential treatment is complete evacuation of the alimentary tract. Constipation is usual, but in the few cases where diarrhoea has occurred I regard this as the attempt of a healthy bowel to expel toxins. Is my theory correct?

A.—Recent evidence has shown that the virus of poliomyelitis appears in the faeces for some days or even weeks after onset of the infection, and that the virus probably reaches the central nervous system from the bowel, since it has been demonstrated in the abdominal sympathetic ganglia. In the pre-paralytic stage of the infection, characterized particularly by fever and irritability, gastro-intestinal symptoms may be present, although they are not usually prominent features. The modern view is that the majority of patients affected with the virus of poliomyelitis develop only these pre-paralytic symptoms, and these cases are called "abortive" poliomyelitis. What determines the development of the paralytic stage in the minority of cases is still unknown, although severe muscular exercise is probably an important predisposing factor. It seems unlikely that purgation or the natural occurrence of diarrhoea in the early pre-paralytic stage will affect the course or severity of the infection.

Physics of Odour

Q.—Is anything known about the physics of odour? We know that sensations of smell are conducted from the olfactory nerve endings, but how do they get there? What sort of particles does the smelling substance emit, and how do they traverse the air? Has any measurement been made of the air content of odoriferous particles? Does an odoriferous substance decrease in weight as a result of emission of such particles? Can they be seen or cultivated?

A.—There is a general belief that material particles of odoriferous substances must come into contact with the olfactory receptors and that the actual stimulation is due to some chemical action. There can be no doubt that the odoriferous substance is carried in the air, but very small weights of such substance may scent a room for years without apparent loss of weight. Threshold concentrations have been measured for some substances, but naturally the threshold varies for different individuals and in the same individual from time to time, but the following threshold concentrations are given: skatol, 3×10^{-11} ; synthetic musk, 4×10^{-11} ; mercaptan, 3×10^{-9} % in air (w/w). The loss of weight of a substance required to give these concentrations in usual surroundings, say a room, although exceedingly minute is nevertheless calculable.

Ichthyosis

Q.—A patient with severe ichthyosis from birth has seemed more normal during hot weather and especially in the Tropics. After return from the Tropics the skin became as bad as ever. On a course of thyroid extract he appeared to be sweating more and his skin became more scaly than usual, but the scales desquamated leaving the skin smooth and almost normal. How much thyroid can I give him, and for how long, apart from looking for symptoms of hyperthyroidism? Will prolonged dosage do harm and will any children be adversely affected? His brother has the same complaint, and his mother has a rough skin but no scaling. Can you suggest any other form of treatment?

A.—Ichthyosis is a congenital abnormality of the skin, often familial, and cannot be permanently influenced by treatment, though some little change occasionally occurs at puberty or the menopause. Thyroid by mouth increases metabolism and sweating and so may produce symptomatic improvement while

the drug is being administered. As a general rule it is wiser to control ichthyosis by local treatment, such as warm-baths and the use of the following ointment:

B	Acid. salicyl.	gr. 10 (0.65 g.)
	Lanolin.	
	Ol. oliv.	
	Glycerin.	āā ad 1 oz. (30 g.)
	Halden's emulsifying base	
	Paraff. moll.	
	Fi. ung.	

There is probably no harm in the prolonged administration of thyroid extract in reasonable dosage, to a total of not more than 1 to 2 gr. (65 to 130 mg.) a day, but it would seem unjustifiable to give larger doses unless there was any indication otherwise of thyroid deficiency. The affection is one that tends to be inherited, and reference should be made to *Inherited Abnormalities of the Skin*, by E. A. Cockayne (1933. Oxford University Press, London).

Chronic Bronchitis and Emphysema

Q.—A man of 72 is subject to chronic bronchitis and emphysema. The attacks started twenty years ago and have since increased in severity and frequency. Iodides, stramonium, and ephedrine have given only temporary relief. Recently it has been necessary to take ephedrine tablets daily, though the effect is less marked than before. X-ray examination of chest is negative. What do you advise?

A.—This description suggests that the patient has chronic bronchitis with attacks in which bronchial spasm is superimposed. In this disorder dyspnoea in the early stages is due mainly to bronchospasm and is relieved by ephedrine. With the passage of years irreversible changes occur in the lung parenchyma, diminishing its elasticity; it is to these that the dyspnoea of the later stages must be ascribed. The history reveals this change, for a dyspnoea on effort is gradually grafted upon, or replaces, the episodic asthmatic breathlessness. Treatment at this late stage is difficult and often unavailing, but the most useful therapeutic measure is the education of the patient, by means of breathing exercises, to use his damaged respiratory apparatus in the most efficient manner possible.

Vitamin D₂ and Pyrexia

Q.—Can concentrated vitamin D₂ cause pyrexia, as well as digestive disturbances? A young woman with pulmonary tuberculosis of four years' standing recently became sputum-positive without increase in radiological signs and with no obvious temperature disturbance. She had a course of calcium and vitamin D₂, but after the sixth dose of the latter pyrexia and general malaise developed. The vitamin was discontinued and after eight or nine days the temperature subsided. Was this coincidence, or could the vitamin treatment have influenced this phase of pyrexia?

A.—Pyrexia has not been reported in patients not suffering from tuberculosis given massive doses of vitamin D. Side-effects such as sweating, nausea, vomiting, anorexia, headache, diarrhoea, and polyuria have been reported after taking very large doses—for example, more than 200,000 units daily over a period. It is not stated in the question how much vitamin D₂ was taken. As the pyrexia occurred only after the sixth dose of vitamin D₂, and as toxic effects result only after prolonged administration of large doses, it is unlikely that the pyrexia in this case was caused by the vitamin.

Gastric Analyses

Q.—Much time is occupied in carrying out large numbers of gastric analyses with test meals. I believe that as much information could be obtained from the fasting juice, after previous preparation of the patient by a stomach wash-out, etc., followed by examination of a sample after administration of histamine if free hydrochloric acid is not found in the fasting juice.

A.—Gastric secretion is a valuable function which may be influenced by many different circumstances. The ordinary fractional test meal is open to so many possible errors that its

value as a diagnostic procedure in cases of uncomplicated peptic ulcer is doubtful. In the investigation of a patient with an anaemia or suspected carcinoma of the stomach, however, a secretion test may be important, and in these instances it is the presence or absence of hydrochloric acid which is looked for. Preliminary lavage may interfere with the secretion of gastric juice and therefore should not be done. No test meal is given, but specimens must be withdrawn at regular frequent intervals for two hours after the injection of histamine, otherwise a minimal response may be missed.

Femoral Thrombosis

Q.—*A woman of 64 had a left femoral thrombosis a year ago, caused by confinement to bed for kraurosis vulvae. She is now quite well except for the leg, which becomes swollen and painful with even mild exercise. What treatment do you advise, and what are the prospects of recovery?*

A.—The condition having settled down, it only remains to deal with the swelling which is the cause of the pain. Bandaging with real elastic bandages (not crêpe) will keep down the swelling below the knees, and that usually suffices. Raising the foot of the bed at night is also very helpful in reducing swelling and cramp. The amount of residual swelling is often greatly reduced by lumbar sympathetic procaine blocks during the active phase of thrombosis, but unfortunately in the present case the opportunity for this helpful procedure has now passed.

Pediculosis Capitis

Q.—*For three months I have been treating a friend who has pediculosis capitis with this mixture: "Lethane 384," 49 parts; ol. petrol. alb., 49 parts; ol. citronel., 2 parts. This has been applied four to six evenings a week after careful removal of nits, but has had no effect beyond reducing the nit population and alleviating scalp irritation. My friend deals with large numbers of children and has taken precautions against re-infection. Can you suggest a reason for the failure of this treatment, and is there one more likely to succeed?*

A.—Some millions of cases of pediculosis capitis have been treated with lethane, and where this has been properly carried out the writer does not know of one instance where three applications have not been completely successful and have not also prevented reinfection. The vast majority of individuals were cured with one application. The questioner here would apparently have made about seventy-five applications and, if he has carried out the proper instructions, will have used some pints of the medicament. The surprising factor is that some alleviation of scalp irritation is alleged, for it is more likely that this gross over-treatment would cause a dermatitis. If the treatment described has failed, no other treatment is likely to be more successful.

Prostatitis

Q.—*What is the treatment of non-specific prostatitis?*

A.—The best treatment ought to be rectal diathermy followed by prostatic massage, but as active infection is present it should be supplemented by the use of one of the sulphonamides.

Chronic Ulcer and Pemphigus

Q.—*A man of 73 has had a chronic ulcer on the left great toe for two years. Culture produced a mixed growth of Staph. aureus and haemolytic streptococci and a heavy growth of coliform organisms. The ulcer was dressed with penicillin cream, and sulphathiazole tablets were given at the same time, but they appeared to cause an acute dermatitis of the foot. Allantoin-sulphanilamide preparations were also tried with the same result. The urine is negative for albumin and sugar. The patient has chronic rheumatoid arthritis, and chronic pemphigus vulgaris of the scalp and front of chest. Can you suggest treatment for this latter condition as well as for the toe ulcer?*

A.—The patient should be seen by a dermatologist. If the diagnosis of pemphigus is confirmed there is no effective treatment and the ultimate prognosis is bad. It is presumed that x-rays have revealed no local cause for the ulcer of the toe. In the absence of organic nervous disease, it is possibly due to

vascular degeneration. Trauma or pressure is another causative factor, and resolution depends on treatment of the cause, which is almost certainly not infective. Cod-liver oil or 0.5% parachlorophenol in a bland base may be used for

Titanium

Q.—*May I have information regarding titanium for clinical use, or details of literature on the subject?*

A.—Titanium dioxide is used in face powders and in toilet articles in place of zinc oxide. Titanium salts appear to diminish erythema and pruritus in certain dermatoses. There is on the market a proprietary desiccant paste for exudative dermatoses, containing titanium dioxide, zinc oxide, and small quantities of purified silicates in a fat-free base. Ointments containing titanium salts are also useful in irritation, dermatitis, localized eczema, syccosis barbae, pruritus after insect bites, erythema of solar dermatitis, and ulceration associated with varicose veins. They are said to be of some value in psoriasis.

NOTES AND COMMENTS

Pink Disease.—Dr. W. G. BRANDER (Rochampton, S.W.) writes: With reference to the answer to the question on pink disease (21, p. 911), I was interested to see that no reference was made to the use of potassium chlorate and acid, hydrochloric dil., as recommended by Peckham in the *South African Medical Journal*, 20, 474. This article was summarized in *Abstracts of Medicine*, 1947, 1, 380. Peckham's treatment is not a direct one to your correspondent, but might be of value to him in the management of his case.

Ejaculatio Praecox.—"V.B.G.-A." writes: Without labouring the point that the wise men came from the East, might I advise the ejaculatio praecox patient referred to (June 28, p. 958) should follow the age-old Oriental practice of anointing the corona with a 1% ung. cocain. just beforehand or, if preferred, with ung. Eucerin. Either damps down the immediate reflex, and it will be found after a few occasions it can be discontinued. I have prescribed scores of times since I was told of it years ago by an ancient Hindu in Calcutta and have never known it fail or give rise to any "harm."

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Commencement of Practice

M. E. has been demobilized and contemplates setting up in general practice. How should he deal with income tax demands for his residence and income not taxed at source?

He is advised to get in touch with the local inspector of taxes, inform him as to the date as from which the practice is commenced, and undertake to supply a statement of account at the end of the first year of the practice. He should complete the form of claim to "married" and children allowance and ask that these allowances be set against the untaxed income, or alternatively that the tax assessed on that income should remain in abeyance until his first year's practice results are known. He will be entitled to deduct as professional expenses a reasonable proportion of Schedule A assessment on the house, of the cost of running the practice (including depreciation) and of such general expenses as cost of domestic service, telephone, etc. Cost of maintenance of instruments, medical library, etc., is permissible, but not the outlay of initial purchase or improvement of such assets. If results of the practice working show a loss relief can be claimed against his own or his wife's taxed income.

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attila Westcott, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcott, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcott, London*. B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 12 1947

British Medical Association

ANNUAL REPRESENTATIVE MEETING, 1947

The Annual Representative Meeting of the British Medical Association will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Tuesday, July 22, and succeeding days.

RESOLUTIONS BY DIVISIONS AND BRANCHES

NATIONAL HEALTH SERVICE ACT

Amendment by MARYLEBONE: That the second half of the third paragraph of Section 20 is an inadequate and therefore misleading account of the events to which it refers.

(The part of para. 20 to which this amendment refers is:

"As a result of the plebiscite, a small majority of the profession expressed themselves against discussions on the regulations. The special Representative Meeting on Jan. 28, 1947, on consideration of the plebiscite results, expressed a willingness that discussions should be entered into with the Minister, provided that such discussions were comprehensive in their scope and that the possibility that they might lead to further legislation was not excluded.")

Amendment by MARYLEBONE: That the following:

"90% of the entire profession took part in this plebiscite. The result of this was that 64% of general practitioners and 55% of the whole profession expressed themselves against discussions on regulations.

"Consequently, the Council drew up a resolution for the consideration of the S.R.M. on Jan. 28, 1947, to this effect. However, at a subsequent emergency meeting the Council withdrew this resolution and substituted one which expressed willingness that discussions should be entered into with the Minister, provided that such discussions were comprehensive in their scope and that the possibility that they might lead to further legislation was not excluded.

"The reason for the change was the belief that the Minister of Health was showing signs of a more conciliatory attitude, as revealed in a letter addressed to the Presidents of the three Royal Colleges. The R.M. were informed of this belief and, in the hope that it was justified, they welcomed the possibility of conciliation and co-operation on the Minister's part so warmly that they passed the resolution by a large majority in spite of the plebiscite figures."

be substituted for the words referred to above.

Report of Negotiating Committee

Motion by NEWCASTLE-UPON-TYNE: That this meeting is of the opinion that the Negotiating Committee should be asked to make in early report of the progress and discussions with the Minister.

Meetings of Local Units

Motion by BATH: That in the event of the Negotiating Committee failing to secure the Minister's agreement to the declared principles, all Divisions of the Association should be asked to meet, in order to instruct their representatives before a special meeting of the Representative Body is held to discuss the terms of a plebiscite. Further, that the Council of the Association should then give a strong lead to the profession in the light of the findings of this special Representative Meeting when issuing the plebiscite forms.

Plebiscite

Motion by BUCKINGHAMSHIRE: (1) That in the opinion of this meeting the result of a future plebiscite be binding on the Council. (2) That, prior to any future plebiscite, the clearest possible exposition of the Association's policy as to the issues involved be circulated by the Council. The actual voting paper should be sent to the voter under separate cover and unaccompanied by any expression of opinion.

Superannuation for Specialists

Motion by DERRY: That the Negotiating Committee be requested to examine the claims for superannuation for specialists retiring from hospital service on the inception of the National Health Service.

Remuneration of Medical Officers Employed by Local Authorities

Motion by LOTHIAN: That the Negotiating Committees in England and Scotland, in their negotiations with H.M. Government,

should endeavour to ensure that the rates of remuneration of all medical officers employed by local authorities should be uniform throughout Britain.

A Rota of Practitioners

Motion by PADDINGTON: That in any National Health Service adequate provision shall be made for a rota of practitioners for duty at night, week-ends, holidays, and during sickness.

Distribution of the Profession

Motion by READING: That, in view of the reason given by the Minister at the second reading of the Act for the abolition of the buying and selling of practices, as being necessary in order to correct maldistribution of practitioners, the Council formulate and publish a positive plan showing how this object could be achieved by other means.

Health Centres

Motion by SOUTHAMPTON: That (1) in view of the fact that the medical profession may be concerned with the staffing of Health Centres to be set up in the National Health Service, it is important that a definite policy with regard to their construction, siting, and organization be adopted, and (2) the Representative Body, instruct the Council to make definite plans regarding the construction, staffing, and functions of Health Centres to be set up in the National Health Service.

Nominations for Statutory Bodies Under the Service

Motion by NORTH STAFFORDSHIRE: That this meeting demands that the profession's nominations to all statutory bodies under the new National Health Service be approved by the Minister of Health.

Motion by TORQUAY: (a) That the Negotiating Committee be instructed to press for a regulation that medical nominations to local Executive Councils be made at a General Meeting of practitioners in the area, serving under the Act. (b) That the majority of medical representatives on local Executive Councils should be in active general practice, whereas on the Regional Boards the majority should be consultants.

Motion by MID-ESSEX: To ensure satisfactory representation of the profession on any of the proposed administrative bodies set up by the Minister, he shall ask the medical practitioners concerned to nominate only as many freely elected representatives as there are vacancies.

Midwifery Services

Motion by STRATFORD: That the Representative Body take the following stand:

1. That all practitioners registered under the present Medical Acts shall be entitled to undertake domiciliary obstetrics under the National Health Service Act.

2. That ten years' experience in domiciliary obstetrics is an adequate preliminary condition of entry to an examination for a postgraduate diploma in obstetrics.

3. That, if the conditions governing examination for existing diplomas cannot be varied in this respect, an appropriate diploma should be newly established.

4. That the above recommendation should be conveyed to the Negotiating Committee.

GENERAL PRACTICE

Fees for Medical Examinations in connexion with Life Insurance

Motion by the CHAIRMAN OF THE GENERAL PRACTICE COMMITTEE: That the following recommendation of Council be adopted:

That Minutes 119-133 of the A.R.M., 1920, and Minute 31 of the A.R.M., 1935, regarding the fees payable for medical examinations in connexion with life insurance be rescinded and the following substituted therefor:

(1) That a "short" form of medical report be approved for use in the case of all insurances where the amount of the policy does not exceed £300, the fee for the completion of this form of report to be 10s. 6d.

(2) That for a medical examination and report in cases where the amount of the policy exceeds £300 the fee shall be £1 11s. 6d.

(3) That no attempt be made to standardize the £1 11s. 6d. form

of report, but that where the form required by the life office is exceptionally extensive a fee of £2 2s. should be payable.

(4) That where, in the case of an insurance for an amount not exceeding £300, the office requires a fuller examination than is provided in the "short" form, the office may use its ordinary form at a fee of £1 11s. 6d.

(5) That in all cases the fee appropriate to the examination, and the amount of the policy, should be printed on the form.

Amendment by BARNSTABLE: That no report to insurance companies by a medical practitioner should receive a fee of less than £1 1s.

Amendment by NORTH STAFFORDSHIRE and WILLESDEN: That the Council be instructed to press for a fee of £2 2s. for medical examinations where the amount of a life insurance policy is £300 or over.

Amendment by TORQUAY: That the fee for the short form of medical report mentioned in sub-para. (1) should be £1 1s. If a more extensive form is required the fee should be £2 2s.

Amendment by WORCESTER and BROMSGROVE: That in the opinion of this meeting, in cases where the policy amounts to £1,000 or over the fee shall be £2 2s.

Motion by MARYLEBONE: That the British Medical Association shall make a recommendation, after consultation with the Life Offices Association, on the question of the payment of fees when proposers fail to keep appointments with doctors.

Fees for Police Calls and for Attendance on Members of Police Forces

Amendment by TORQUAY: That in view of the discrepancy in the time between paras. 22 and 88 of Council's Report, the time has come when the hours constituting day and night visits should be standardized.

Amendment by TORQUAY, and KENSINGTON AND HAMMERSMITH: That the hours constituting a day visit should be 9 a.m. to 8 p.m. and the night visit 8 p.m. to 9 a.m.

Fees for the Administration of Anaesthetics to Persons receiving Dental Treatment as an Additional Benefit under the National Health Insurance Acts

Motion by the CHAIRMAN OF THE GENERAL PRACTICE COMMITTEE: That the following recommendation of Council be adopted:

That where practitioners are requested to administer anaesthetics to insured persons receiving dental treatment as an additional benefit under the National Health Insurance Acts, the following fees should be paid:

For the simple administration of nitrous oxide or similar anaesthetic:

5s. per administration, for the extraction of:

1-5 teeth	10s.	6d.
6-10 teeth	£1	1s. 0d.
11-20 teeth	£1	11s. 6d.
21 or more teeth	£2	2s. 0d.

always provided that an increased fee shall be payable in specially difficult circumstances.

Amendment by CARDIFF: That the recommendation be referred back for further consideration, with a view to the introduction of a flat rate.

Fees for Medical Certificates under the Lunacy and Mental Deficiency Acts, and for Recommendations under the Mental Treatment Act

Motion by the CHAIRMAN OF THE GENERAL PRACTICE COMMITTEE: That the following recommendation of Council be adopted:

(i) That the existing policy of the Association relating to the fees for medical certificates under the Lunacy and Mental Deficiency Acts, and for recommendations under the Mental Treatment Act, be rescinded:

(ii) That there be substituted therefor the following:

(1) *Fees for Medical Certificates under the Lunacy Acts:* A fee of at least two guineas should be paid.

(2) *Fees for Medical Certificates under Mental Deficiency Act:* The fee for medical certificates under the Mental Deficiency Act, signed by the "usual medical attendant," should not be less than two guineas.

(3) *Fees for Recommendations under Mental Treatment Act:* In cases where a "recommendation" is made under the Mental Treatment Act for a private patient the fee should be a matter of arrangement between the relatives and the practitioner concerned, but in public assistance cases a fee of not less than two guineas would appear to be appropriate.

Amendment by DERBY: Fees for medical certificates under the Lunacy Acts—a fee of at least two guineas should be paid (1) whether the certificate is completed or not, (2) whether the certificate is completed and the patient is discharged by the Justice.

"Doctor" Signs on Cars

Motion by KENSINGTON AND HAMMERSMITH: That with reference to para. 28 of Annual Report of Council further action be taken with a view to securing the removal of all "doctor" signs from cars.

Supplementary Clothing and Other Coupons

Motion by SWANSEA: That, with reference to para. 37 of Council's Report, appropriate action be taken to secure a freer issue of gowns in view of the fact that when coupons are presented found that they cannot be honoured. The same applies with reference to rubber gloves.

Fees for Mileage and Visits for Local Authorities and Government Departments

Motion by BARNSTABLE: That fees paid by public authorities including Government Departments, for mileage and visits should be standardized.

Public Medical Service: National Deposit Friendly Society

Motion by DARTFORD: That the present rates of payment under the Public Medical Service and the National Deposit Friendly Society be reconsidered in view of increased cost of drugs, etc., so as to compare with the higher fees now paid for other medical services of a like nature.

Reports to Coroners

Motion by DERBY: That when a practitioner is requested by a coroner to furnish him with a medical report in respect of a deceased person for whom a death certificate cannot be supplied in the usual manner, the coroner shall pay the practitioner a fee of one guinea for such a report.

Motion by ROCHEDALE: That steps be taken by the Association to secure payment on a uniform scale for medical reports to coroners in all cases.

The Scope of General Practice

Motion by LEEDS: That the Council be instructed to resist to the utmost any attempt to diminish the present scope of general practice.

Doctors' Cars

Motion by GREENWICH AND DEPTFORD: That this meeting is satisfied with the present arrangements made by the Association for obtaining doctors' cars, and urges the Council to take appropriate action to secure definite priority.

Doctors' Evening Surgeries

Motion by SHEFFIELD: That this Representative Meeting considers that the time has now arrived when it is no longer in the public interest that doctors' evening surgeries should continue to the present late hour. There should be an immediate review of times of surgeries.

Certification

Motion by ABERDEEN AND KINCARDINE COUNTIES: That this meeting, while appreciating the need for certification during present world shortages, deplors the increasing number of certificates which doctors are asked to give, and recommends that in future all demands for further certification should be submitted to a committee of the General Practice Committee and passed only if reasonable before the profession is asked for these certificates.

NATIONAL HEALTH INSURANCE

Medical Records of Demobilized Persons

Motion by WORCESTER AND BROMSGROVE: That with reference to para. 53 the Council be asked to investigate the legal position as to the use of these medical records for any purpose which is for the benefit of the patients, including pensions appeals.

Certification

Motion by PADDINGTON: That, with reference to para. 55 of Council's Report, certification shall only appertain to the witness of a signature and not vouch for the accuracy of the material contents of the said certificate.

SPECIAL PRACTICE

Rules for the Government of Groups and Consultants' and Part-time Consultants' Rolls

Amendment by WORCESTER AND BROMSGROVE: That, with reference to para. 62 of Council's Report, this meeting, being desirous that the views of part-time consultants and specialists should receive adequate consideration, is of the opinion that membership of Consultant and Specialist Groups should be open to members of the part-time Consultants and Specialists Roll.

Salaries of E.M.S. Specialists

Amendment by WORCESTER AND BROMSGROVE: That, while approving para. 68 of Council's Report as a step in the right direction, this meeting is of the opinion that the increases allowed are insufficient and should be accepted only on the understanding that such acceptance is without prejudice to scales of remuneration in any future health service.

Access to Ancillary Departments of Hospitals

Amendment by GREENWICH AND DEPTFORD: That, with reference to para. 71 of Council's Report, this meeting regrets the obscurity of Council's recommendation and feels that until ancillary departments are adequately staffed the "open door" policy is fraught with danger.

HOSPITALS*Shortage of Nurses*

Motion by KENSINGTON AND HAMMERSMITH: That Council should ask the Minister of Health to give urgent attention to the solution of the problem created by the grave shortage of nurses, since it is affecting the health of the nation.

Remuneration of Practitioners holding Junior Hospital Posts

Motion by PLYMOUTH: That the present remuneration for junior hospital posts is entirely inadequate and the British Medical Association should formulate a scale of salaries for adoption by all hospitals.

PUBLIC HEALTH*Practitioners Employed Part-time by Local Authorities*

Amendment by EAST YORKSHIRE: That the Annual Representative Meeting, 1946, having approved the recommendations of Council relating to a minimum scale of fees appropriate to part-time medical work on a sessional basis, this meeting views with dismay the action of Council in propounding a lower scale of fees to which its negotiations with other bodies would appear to have committed the profession, repudiates such action as prejudicial to the present and future interests of the profession, as well as a betrayal of the mandate sought by the Council and accorded at its request, and reaffirms resolution 100 of A.R.M., 1946.

Amendment by NEWCASTLE-UPON-TYNE: (1) That the mileage fee for consultants agreed at the A.R.M., 1946, is inadequate and should be increased. (2) That a consultant called to an emergency case for consultation followed by operation should receive a consultation fee in addition to the mileage and operation fees.

Trade Union Membership

Motion by GATESHEAD: That the attention of the Minister of Health be drawn to the flouting of his recommendation as to the non-enforcement of the "closed shop" principle, as applied to doctors, by various local authorities in the country.

Salaries in Public Health Service

Amendment by NORTH STAFFORDSHIRE: That the Council be instructed to reconsider the minimum salaries for whole-time consultant and other appointments.

Motion by CARDIFF: That, with reference to para. 80 of Annual Report, when the revision of the Askwith scale of salaries in the Public Health Service takes place the new scale should be retrospective from April 1, 1946.

Motion by GATESHEAD: That the inadequacy of the present salary award to whole-time Public Health Medical Officers be emphasized and that care should be taken in future negotiations that any salary scale for whole-time officers be considered in relation to increases in fees payable for part-time Public Health and Hospital work.

Milk

Motion by HARROW: That, with reference to para. 84 of Council's Report, this meeting considers that the breadth of the problem demands consideration by an Inter-Departmental Committee of the Government, including the Ministries of Food, Agriculture, Health, and any other Department concerned with the production and distribution of milk; and requests Council to press the Government for the appointment of such a Committee.

Motion by MARYLEBONE: That this meeting wishes to impress upon the Minister of Health the urgent necessity of action by the combined efforts of the Ministers of Health, Food, and Agriculture in order to ensure that clean safe milk is made available as efficiently as possible.

FINANCE*Subscription to the Association*

Amendment by GREENWICH AND DEPTFORD: That this meeting is of the opinion that the time has now arrived when an increase in present subscription rates should be considered.

MEDICAL ETHICS*Rules of the Central Ethical Committee relating to Complaints regarding Professional Conduct*

Amendment by NEWCASTLE-UPON-TYNE: That this meeting agrees to the expulsion of a member who has accepted an appointment subject to an important notice in the *Journal*, but that all other cases of ethical conduct should originate in the Branch or Division.

ORGANIZATION*Expenses of Members attending Meetings*

Motion by GREENWICH AND DEPTFORD: That this meeting approves the principle of payment of expenses of members attending meetings, but considers that the rates suggested by the Organization Committee are inadequate and would still debar the younger member accepting office, and recommends that they be doubled.

(Note: The rates suggested by the Organization Committee were as follows:

That, in addition to first-class return railway fares (including sleepers), payment of subsistence allowances be made to members of the Association attending centrally arranged meetings on the following basis:

For absence from home over 8 hours	10s. 6d.
Where stay overnight is necessary an additional	£1 0s. 6d.
Where a sleeper is claimed the overnight payment to be reduced to	10s. 6d.

Where attendance on consecutive days does not necessitate the use of hotel accommodation payment on the day basis only to be made.)

Motion by GATESHEAD: That, with reference to para. 96 of the Annual Report of Council, payment of representatives attending central meetings should be on a factual basis of actual submitted expenses up to a predetermined maximum.

Motion by LEEDS: (1) That Representatives, Members of Council and members of Standing Committees or other Committees or meetings for the conduct of business of the Association arranged centrally be paid out of the general funds of the Association subsistence allowance at a rate to be determined by the Representative Body from time to time.

(2) That By-law 86 be amended to read as follows:

The expenses of any person which in pursuance of the 49th Article of Association are to be defrayed out of the general funds of the Association are the first-class travelling expenses (including where necessary the cost of a sleeping berth) within Great Britain and Northern Ireland of that person together with such allowance for subsistence as may be determined by the Representative Body from time to time.

(3) That the subsistence allowance payable to members under By-law 86 shall be as follows:

1. For each day on which the member shall be engaged away from his practice for not less than 8 hours between 8 a.m. and 8 p.m.	10s. 0d.
For each night spent in travelling	10s. 0d.
For each night where it is necessary to stop in a hotel	£1 0s. 0d.

GENERAL MEDICAL COUNCIL*Election of a Woman Practitioner as a Direct Representative of the Profession on the General Medical Council*

Amendment by PLYMOUTH: That the existing procedure is adequate to ensure that a woman can be elected to the G.M.C. on her merits.

PUBLIC RELATIONS*Information Service at B.M.A. House*

Motion by BATH: That the Public Relations Committee of the Association be urged to encourage its activities in giving to the public authoritative information on hygiene and medical progress such as is obviously popular when supplied by other agencies.

EXECUTIVE COUNCILS IN SCOTLAND

The Secretary of State for Scotland has fixed the areas that the 25 Executive Councils will administer under the National Health Service (Scotland) Act. Glasgow, Edinburgh, Dundee, and Aberdeen will each have an Executive Council, as will the counties of Angus, Ayr, Caithness, Dumfries, Dunbarton, Fife, Inverness, Lanark, Orkney, Renfrew, Ross and Cromarty, Sutherland, and Zetland. An Executive Council will be appointed to each group of counties as follows: Aberdeen and Kincardine; Argyll and Bute; Banff, Moray, and Nairn; Kirkcubright and Wigtown; Midlothian, West Lothian, East Lothian, and Peebles; Perth and Kinross; Roxburgh, Berwick, and Selkirk; Stirling and Clackmannan. The members of the Councils are expected to be appointed in a few weeks' time.

MEDICAL ORGANIZATION IN DENMARK THE STATE SERUM INSTITUTE

BY

PETER KRAG

Head of Department, State Serum Institute, Copenhagen

The State Serum Institute was established in 1902. The main object was the production of diphtheria antitoxin serum, but it was intended to take up similar work on other diseases according to the possibilities arising. Since then its development has been stamped by the Institute's being the sole central laboratory for diagnostic bacteriology and serology in the country. Besides considerable extension of the diagnostic work the Institute comprises larger and smaller factory-like plants for the production of sera and vaccines, and in connexion with these much scientific work is carried on—applied science as well as pure research.

The diagnostic work is arranged in several departments. A department for general bacteriology carries out all diagnostic bacteriology, including Widal and Bunnell tests; the tuberculosis and pneumococcus diagnoses are undertaken in separate departments, where also the production of tuberculin and anti-pneumococcal sera is carried out; a serodiagnostic department is responsible for the serological diagnosis of syphilis and gonorrhoea. Further, there are a special department for blood typing and dried serum production, and a hormone department (9,000 tests for pregnancy in 1945). Production proper is managed by the serum department (diphtheria antitoxin and vaccine; convalescent sera), the anaerobic department (other sera), and the vaccines department (smallpox vaccine and bacterial vaccines). The Calmette vaccine is produced in the tuberculosis department (40,000 persons vaccinated during 1945). In connexion with serum production a physico-chemical department performs concentration of the sera. All the finished products pass through a control department. Two special departments take care of the international work carried out at the Institute, namely, the department for standardization of sera and toxins, and the Salmonella Centre. There is a considerable plant for the production of foot-and-mouth disease vaccine. Virus research, which is going on in two or three departments, has not yet a department of its own.

Common to these special branches are the administration, library, stables and farming, and departments for medium preparation, cleaning, workshops, supplies, etc.

Diagnostic Service

Any doctor and any hospital have the right to send samples to the Institute for diagnostic purposes, and they may requisition packing and blank forms free of charge. All tests of importance for the control of epidemic disease are carried out gratis, while prices for other tests have been fixed in accordance with the actual expenditure of the department in question, given in a quarterly note of account. Payment follows from the hospitals directly (i.e., from the commune or county in question). Doctors are liable for tests carried out in connexion with private practice, but have a right to charge the cost with their fee. In panel practice the doctor simply fills in the name of the panel on the form, and the panel gets a quarterly note of account covering the investigations requisitioned by a number of panel doctors.

Every doctor in the country gets an annual survey (in the Organization's *Pocket Book*) of the diagnostic facilities offered; together with a list of prices. Applications for free investigations may be met in the case of research work or if the patient is poor.

Samples are received throughout the twenty-four hours. Serological investigations are started at 10 a.m. (Widal tests repeatedly during the day); bacteriological examinations are taken from 9 a.m. to 11 p.m.; particularly important samples are dealt with during night hours also. The results are sent by mail; but telephone and telegraph are used in accordance with doctors' wishes and whenever it is deemed necessary by a positive finding of, for instance, typhoid bacilli. With each

answer, on the back of the form, an explanation of the result obtained is given, and the diagnostic consequence likely to ensue is suggested.

As the size of the country in relation to the railroad system makes it possible for samples to reach the Institute within six to eighteen hours, the whole area of Denmark is covered, even the remotest corners of Jutland. It is true, however, that doctors in some parts of the country have to take a sample from their patients (e.g., for gonococcus culture) just before the train leaves.

The departures from the system of centralized diagnosis are few and may in part be looked upon as virtual outposts of the Institute: (1) Many doctors do their own microscopy with regard to gonorrhoea and tuberculosis. (2) Most clinical laboratories (in the hospitals) manage the diagnosis of *Bac coli*, staphylococci, etc., in cultures from urine and pus, and the microscopical diagnosis of gonorrhoea and tuberculosis. (3) Most hospitals diagnose diphtheria by the culture method. (4) The Institute has for some years run eight auxiliary laboratories for pneumococcus typing, and one for gonococcus diagnosis by culture. These provisional laboratories are being developed at present.

As the culture methods are vastly superior to microscopy for gonococci and tubercle bacilli, there is an increasing demand that samples should go direct to the Institute in order to secure the best possible basis for diagnosis and control. As for diphtheria, the Institute is the only place where type and virulence can be ascertained.

Material for Education and Records

Material from the Institute is utilized by the university in the training of medical students, and its routine methods are taught. It is a rule that alterations occurring in the diagnostic method are described and accounted for in the Organization's weekly *Ugeskrift for Læger* (corresponding to the *B.M.J.*). A post graduate course is usually held at the Institute annually. It is attended chiefly by a few doctors wanting to specialize in research work or who require an addition to the hospital training.

As the Danish population is rather small, about four million a survey is manageable, and the Institute is able to run a series of indexes, comprising, for instance, all typhoid and paratyphoid carriers, all tuberculous patients, all syphilitics, all patients with a positive gonococcus complement-fixation reaction or positive gonococcus culture, and all members of authorized blood donor corps. These indexes are kept up to date from the results registered in the various departments and by means of compulsory notification from practitioners and from hospitals, sent through medical officers. The indexes give information to any doctor inquiring into the case history of a patient, and in return are provided with the information necessary for registration and classification. The Institute receives ten to forty inquiries daily by letter or telephone from doctors wanting advice on diagnosis and therapeutics—which tests should be used in a certain case, how a result should be interpreted, or what is the correct use of the Institute's sera and vaccines. Some of the questions, however, are referred to specialists among the chief physicians or professors in the capital.

Sera and vaccines are distributed to hospitals, clinics, and doctors upon written or telephoned requisition at any time of the day or night. Payment follows the rules for diagnostic investigations mentioned above. Since the panel institutions refuse on principle to pay for any prophylactic measure—some of the vaccines form exceptions to the rule—the patients have to pay themselves. Diphtheria vaccine, however, is free of charge; and, as for vaccination itself, a law was passed a few years ago fixing doctors' fees and stating what public institutions are liable for payment.

Income and Expenditure

The size of the Institute appears from the following figures for 1945-6.—Employees: laboratory, 249; administration, stables, cleaning, workshops, etc., 379. Income: about £150,000; expenditure: about £300,000. The annual deficit is

met by Parliamentary vote; the cost of new plants and buildings is covered by special grant.

The number of samples received per year approaches one million, divided into groups as follows: bacteriology, 300,000; serology, 500,000; others, 100,000.

Public Health and Research

A central institute is an immensely valuable organization, when the size of the population is less than five to six million and proper means of communication are at hand. It means that all diagnoses become comparable. It is easy to maintain a high technical standard, since the use of controls necessitates only a proportionately small amount of work. The doctors and hospitals can send the day's diagnostic material in one package. The Institute receives a large and uniform quantity of material suitable for the evaluation of practical routine work as well as for research. It is also possible for the staff to survey diagnostic and epidemiological problems of the whole country; and therefore the State epidemiologist, who is called for as adviser to the medical officers whenever an epidemic shows signs of becoming serious, has his daily activities divided between the Board of Health and the Institute.

The following are minor disadvantages of the centralized work: the large scale on which the work has to be done is accomplished only by means of a somewhat factory-like organization, and a certain skeleton-like treatment of the individual sample may ensue; unfortunately, also, the subordinate laboratory personnel have a very monotonous and unqualified task. The staff may find it difficult to keep abreast of the scientifically important material accumulating.

Research work is considerably furthered by the possibilities for team work naturally afforded by a branched and full-grown central institute providing efficient and highly qualified technical assistants in many fields. Problems of room and personnel may here be more easily settled since not all departments are fully loaded at the same time. But, on the other hand, if planning for extensions and new buildings is neglected the resulting disadvantage is considerably more serious than in the case of minor laboratories, where the difficulties may perhaps be overcome by the addition of an extra room or two. Further, an independent, central institute with a monopoly may lead to stagnation, since criticism and new ideas are seldom brought forward or perhaps dismissed as not well founded. A fruitful scientific reciprocal relation can be established only with similar institutes in foreign countries.

The leading posts of the Institute are filled by physicians and pharmacists who are permanent functionaries; all have to regard the Institute situation as full-time employment not allowing any paid extra job. This means that at the age of 40-45 they have become specialists within a narrowly limited field and have very little opportunity indeed for obtaining favourable conditions elsewhere. This feeling of dependency is to some extent compensated by the excellent access to scientific work offered by the Institute—in theory. In practice, long periods of necessary routine work together with want of space may tend to diminish the possibilities for research work. To our young medical assistants an appointment of from two to four years means a valuable scientific scholarship, since the routine work they are called upon to carry out can be accomplished within three or four hours of the day, while culture media, chemicals, animals, etc., are placed at their free disposal—granted of course that the principals approve of the research plan in question.

Freedom from Financial Profit

In my opinion it is an essential advantage that the Institute is not a private enterprise with a demand for a certain annual balance, since this might lead to a price policy obstructing many useful investigations of importance to the patients as well as to science. If the standard of scientific work in a country's sole central institute can be maintained equal to that of other countries, and if the institute's daily experience is utilized in the right way, the central institute constitutes the most economical and manageable solution to the practical and scientific problems connected with bacteriology and serology.

RELEASE FROM THE FORCES

The following is the latest information received by the Central Medical War Committee on the arrangements for the release of medical officers in Class A.

Royal Navy.—July 1-Aug. 31: Group 62; Sept. 1-30: Group 63.

Army.—General Duty Officers: July 1-Aug. 15: Group 60; Aug. 16-Sept. 30: Group 61. Specialists: July 1-31: Group 51; Aug. 1-31: Group 52; Sept. 1-30: Group 53.

Royal Air Force.—July 1-31: Group 60; Aug. 1-31: Group 61; Sept. 1-30: Group 62.

HEARD AT HEADQUARTERS

Self-certified

In the strange retort houses of the Ministry of Fuel and Power the ancient taunt, "Physician, heal thyself," becomes not a taunt but an injunction, "Physician, certify thyself." A correspondent raised with the Ministry the question of space heating in doctors' surgeries and asked about the necessary authority for such heating. He received in due course a reply from the Parliamentary Secretary stating that it was assumed that the reference was to a room in the doctor's own house which he used as a surgery. "If this is the case the use of gas or electricity, where necessary in the interests of his patients' health, can be covered by a certificate issued by himself." Then there followed the usual reminder of the need for economy. The certificate, presumably, will be something to this effect: "I, John Brown, certify that I, John Brown, am entitled to use a gas fire in my surgery." To whom is this certificate to go? Who is to "vet" it? What penalties are to be imposed if it is "untrue, misleading, or improper"? If a doctor who is himself neither a septuagenarian nor an infant (the certificate of course should be specific on that point) switches on his electric radiator, does the filling up of a certificate by himself legalize an illegal act? Where is the line to be drawn? May a doctor, on the ground that his own well-being is necessary to the health of his patients, certify himself as eligible for extra rations? This is surely another instance of the faith in form-filling which has descended on official bodies. Everything is all right if it is vouched for on the dotted line.

No Parking

The no-parking rule in certain streets in West and Central London has its advantages in speeding up traffic, but it can be very inconvenient to a doctor if he is required to park his car a considerable distance away from the premises to which he has been called. Fortunately the streets affected by the new order are mostly non-residential; nevertheless, doctors are called in emergencies to business premises. The Association has asked the Commissioner of Metropolitan Police whether a practitioner who is called to a sudden emergency may be allowed to park his car in the prohibited area. An ambulance is permitted to stop in a no-parking street, and the doctor on an emergency call is on no less important an errand.

Scotland under Dissection

The Registrar-General for Scotland described to the Royal Statistical Society the other day the projected third Statistical Account of Scotland, which is being undertaken through the generosity of the Nuffield Foundation. The first Statistical Account was completed at the beginning of the nineteenth century, and the second in 1845. It is much more than a census: it is a collection of information on the way of life of each local community, the attitude of the people to work and leisure, the changes in public and social services, and it includes local customs and traditions, local ballads and sayings, and even medicinal cures or food recipes which are peculiar to the parish under review. Four preliminary surveys are already being undertaken, each under the special supervision of one of the Scottish

universities—namely, in the counties of Ayr, East Lothian, and Fife, and the city of Aberdeen. For this purpose the goodwill of many national and local bodies in Scotland has been secured, among them the Scottish Council of Social Services, the Convention of the Royal Burghs, the Association of County Burghs, educational institutes, and the presbyteries. Clergymen of every church, teachers of every school have been asked to co-operate. It was curious that not a word was said by the Registrar-General about the help which medical practitioners and medical officers of health could give in such a survey. Very possibly such help has been enlisted, but it was not mentioned. The doctor knows the lives of people behind doors which may be closed to ministers of religion. No one has a better knowledge of the domestic background to the social scene.

Correspondence

Buying of Practices

SIR,—In answer to my letter published in the *Supplement* of June 7 (p. 116) Dr. J. Michael Jones states (*Supplement*, June 21, p. 153) that I repeat the glib statement that up to 100% of the price of a practice may be obtained at low rate of interest; he had heard this stated so frequently, usually by old practitioners, etc. I must refute his statement, which I am in a position to do authoritatively, having recently availed myself of one of the schemes available. The bank did not require a guarantor. All the bank required was a life assurance policy to cover the amount of the loan, which policy had no surrender value, having been recently taken out, an assurance of personal integrity, and a copy of the audited accounts of the practice over the past six years. The bank take a charge on the goodwill of the practice and an assignment of the life policy; repayment is over ten years usually, but may in a few cases be extended to fifteen.

When one considers that a building society will usually loan 90% of the cost of a house over 20 years, it will be seen that very little capital is actually necessary for the purchase of a house and practice, and not many years of assistantship would be necessary to acquire these means.

It seems possible to me that the Treasury hope to make more than the 4% p.a. on medical practices after they have "over."—I am, etc.,

Wales,

T. H. HARGREAVES.

SIR,—With reference to Dr. J. Michael Jones's letter (*Supplement*, June 21, p. 153) concerning the buying of practices, I would point out that last year I borrowed 100% of the amount to buy my practice without security save for £300 of saving certificates. The latter I need not have given, but I preferred to do so. The loan was arranged by a firm that advertises in the *Journal*, and my bank advanced the money. The same bank allowed an overdraft of £300, to run if necessary for five years. The loan is to be repaid in 15 years, interest being 4% per annum.

I have since borrowed a further substantial sum to buy another share in a practice, and this was arranged in five minutes over the telephone. References are of course required, but the only one I gave was from my former Army A.D.M.S. The only other condition is that a life insurance equivalent to the amount borrowed has to be held by the borrower. I should perhaps add that other firms are less obliging.—I am, etc.,

Newport Pagnell, Bucks.

A. A. CLAY.

Extension of N.H.I.

SIR,—Dr. A. Crawford Mayer (*Supplement*, June 21, p. 153) comments on the N.H.I. Service. His suggestions, and others, are to be found in "The B.M.A.'s Proposals for a General Medical Service for the Nation" (1930). I would like to know why the B.M.A.'s admirable plan has attracted so little attention.—I am, etc.,

Chichester, Sussex.

G. T. RUTHERFOORD.

Association Notices

PROPOSED WEST WIGTOWNSHIRE DIVISION

Notice is hereby given by the Council of the Association that it is proposed to form a separate Division composed of members of the Association in West Wigtownshire (at present included in the Dumfries and Galloway Division and form part of the Border Counties Branch), and to attach this Division to the Glasgow and West of Scotland Branch, area of the Division being defined as follows: Wigtown, with the exception of the parishes of Glasserton, White Sorbie, Kirkcinner, Wigtown, and Penninghame. The area of the Dumfries and Galloway Division to be consequently amended.

Any member affected by the proposal and objecting thereto is requested to write to the Secretary by Aug. 12 stating objection and grounds therefor.

CHARLES HILL,
Secretary

Diary of Central Meetings

JULY

- 22. Tues. Council, 11 a.m.
Annual Representative Meeting, 2 p.m.
- 23. Wed. Annual Representative Meeting, 10 a.m.
Annual General Meeting, 12.30 p.m.
- 24. Thurs. Annual Representative Meeting, 10 a.m.

Branch and Division Meetings to be Held

EAST YORKSHIRE BRANCH.—At Quern House, Park Street, H. Tuesday, July 15, 8 p.m. Discussion of agenda of Annual Representative Meeting and instruction of Representatives. Saturday July 26, 3 p.m. Visit to "The Retreat," Haslington Road, York.

ISLE OF WIGHT DIVISION.—At Royal Isle of Wight Convalescent Nurses' Home, Adelaide Place, Ryde, Monday, July 14, 8.15 p.m. Dr. L. A. Hulst (Dean of University Hospital, Utrecht) "Experiences of Medicine in the Occupied Netherlands."

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Chancery Cross Road, W.C., Thursday, July 17, 8 p.m. Agenda: Consideration of Supplementary Report of Council for 1946. To formulate amendments to published motions on agenda for A.R.M.

Meetings of Branches and Divisions

EDINBURGH AND SOUTH-EAST OF SCOTLAND BRANCH

Dr. P. Martin Brodie, retiring President of the Branch, and his friends received a large gathering of members and their friends at the Hall of the Royal College of Surgeons, Edinburgh, for the Annual Summer Meeting of the Branch on June 25. In welcoming the guests Dr. Brodie expressed to the President and Council of the Royal College the sincere appreciation of the Branch for the great privilege of being allowed to hold their meeting in the honourable precincts of the College. In replying, Mr. J. M. Graham, President of the Royal College of Surgeons of Edinburgh, hoped that it might be the first of many future occasions when members of the British Medical Association would be welcome guests.

Dr. Douglas Guthrie, Honorary Librarian, gave an entertaining account of the history and traditions of the ancient College from its foundation in 1505 to modern times. The social activities culminated in a sumptuous tea with strawberries and cream. At the reception the Annual Meeting of the Branch was held, the main business being the election of office bearers, with Dr. G. W. Ireland as the new President.

SOUTH-WESTERN BRANCH

The 107th Annual Meeting of the South-western Branch was held at Torquay on June 12, when Dr. F. D. M. Hocking, Truro, resigned the chair to Dr. P. A. McCallum, of Torquay. Dr. McCallum gave his inaugural address on "The Practice of Medicine in Retrospect and Prospect." He said that they stood to-day at the close, or very near the close, of an era in medical history. They saw themselves threatened with governmental control becoming the servants of the State rather than the servants of the patients.

At this critical phase in the history of medicine what could they do to be saved? First, they must at all costs retain and safeguard their individual freedom to deal with their patients as they believe to be best. There must be freedom of judgment, action, speech, and publication. Secondly, if they were to retain their freedom probably one of their greatest needs was unity. The diversity of activities and interests within the profession made that difficult. They needed more opportunities for friendly intercourse and for discussion of their general and individual problems. Thirdly, they must preserve a due sense of proportion, uninfluenced by personal idiosyncrasies, personal likes and dislikes. And fourthly, their public relations must be developed and improved.

LONDON SATURDAY JULY 19 1947

SOME ASPECTS OF HUMAN INFERTILITY

BY

ALBERT SHARMAN, M.D., Ph.D., B.Sc., M.R.C.O.G.

Senior Assistant Surgeon, Royal Samaritan Hospital for Women, Glasgow

Although infertility is one of the oldest of human problems it is only within the present century that real progress has been made in its study. But in these comparatively few years intensive work has been done on this subject, and the accumulated literature is now enormous. It is not my intention to refer to more than the essential relevant writings or to give an exhaustive account of the complete investigation and treatment of a barren marriage. It is proposed, rather, as indicated in the title of the paper, to discuss certain selected aspects of the subject which have been under personal study and investigation during recent years—namely: (1) The tubal status—patency and non-patency—as determined by insufflation in a consecutive and unselected series of 1,478 cases of primary sterility. (2) Therapeutic aspects of insufflation, based on 271 cases of pregnancy following insufflation in primary sterility. (3) Tuberculous endometritis and primary sterility—a study of 100 cases (the largest series ever recorded). (4) The causation of tubal occlusion.

The Tubal Status

Patency of the lumen of the Fallopian tube is an obvious essential to conception. But the tube is not a static entity: not only does its muscular coat undergo peristaltic movements but its fibres increase and decrease in length with the phases of the cycle. Guthmann (1922) was the first to record the fact that tubal peristalsis was responsible for the nanometric fluctuations on insufflation, and he based his conclusions on the fact that when the tubes were closed these fluctuations were absent. Müller (1944) has shown by hysterosalpingograms that peristalsis occurs in the tubes, both in the direction of the uterus and from the uterine end towards the fimbriae. In two cases of sactosalpinx he demonstrated that iodine masses moved from place to place as the result of peristalsis and antiperistalsis. Peristalsis has been observed by Westman (1930) in the monkey and by Mikulicz-Radecki and Nahmmacher (1926) and by Siegler (1944) in the rabbit. Peristaltic movements or contractions in the human tube had never been directly visualized until August, 1946, when I observed them during the course of an operation for the removal of a diseased ovary. I had been utilizing the opportunity for studying the effects of insufflation (per vaginam) on the tubes when their fimbriated ends were clamped. As soon as the pressure forceps were released peristaltic movements in the direction of the fimbriated ends were clearly seen and demonstrated to the assistant, house-surgeon, and anaesthetist. These movements were seen in only one of nine such experiments. As Ruddick (quoted by Siegler, 1944) has failed to notice any tubal peristalsis on peritoneoscopy in over 2,000 cases,

it is probable that the non-physiological conditions imposed by experiment were responsible for inducing peristalsis in my case.

Since the functional condition of the tube to a large extent determines the chances of fertilization it is obviously desirable to investigate this aspect of the reproductive mechanism. Although the available methods are not physiological they have the advantage of being easy to apply and of yielding sufficiently accurate information for clinical purposes. They should be adopted as part of the routine examination of the wife, for impairment of tubal function cannot be excluded by the ordinary bimanual examination, however carefully conducted.

The methods in general use fall into two main groups—those designed to investigate the passage of a gas through the genital tract (utero-tube insufflation) and those in which the condition of the tubes is revealed by their radiographic appearances after the injection of a suitable opaque substance (hysterosalpingography). It is proposed here to discuss only insufflation, for which purpose various types of apparatus have been described since the introduction of the method by Rubin in 1919. The outstanding advance in recent years has been the inclusion of the kymograph, which makes possible the registration of tubal contractions and thus takes into consideration the actual behaviour of the tubes during the test. Four types of record are obtained, corresponding to the following conditions: normal tubal patency, tubal spasm, tubal stenosis, and non-patency.

The total number of patients in the series whose tubes were insufflated amounted to 1,478, of whom about 400 had two or more insufflations. In most instances the test was repeated simply as a confirmatory procedure; in some it was done to compare the findings with and without anaesthesia; but in 22 patients six or more tests were done to study the behaviour of patent tubes over a considerable period of time. One patient was insufflated 23 times over a period of seven months and another daily for the 18 days between the conclusion of one period and the beginning of another.

A study of the behaviour of patent tubes as revealed by repeated insufflations shows that under similar conditions—for example, the consistency of the rate of flow of the gas—there is a noteworthy constancy in the appearance of the tracings obtained. No great difference, either in the level at which patency is established or in the appearance of the tubal contraction waves, is usually seen in any given patient when insufflation is repeated even after several months. Increase in the rate of flow of gas is sometimes followed by a great increase in the patency-pressure level and by more active deeper peristaltic waves, but this is not invariable. Around ovulation time (presumptive) more active or more frequent peristalsis may occur. This also

*Being the substance of a paper read, by invitation, at the South African Medical Congress, Durban, October, 1946.

THE EVOLUTION OF CLINICAL MEDICINE AS ILLUSTRATED BY THE HISTORY OF EPILEPSY

BY

GORDON HOLMES, M.D., F.R.C.P., F.R.S.

To all who have been for some years engaged in the practice of clinical medicine it is obvious that important developments in the diagnosis of many diseases have taken place during the period of their professional life, but many are apt to forget now recent is the acquisition of much knowledge. Hughlings Jackson, to whom I was house-physician, was accustomed to say he had been a neurologist many years before the knee-jerk was first described, and I had almost passed out of studentship when Babinski drew attention to that type of pathological plantar reflex which has become such a valuable sign in the diagnosis of nervous disorders. Advances in treatment are perhaps more striking, but as rational therapeutics depend on recognition of the nature of the disease, diagnosis is evidently the first essential step in progress.

In many instances recognition of the nature and origin of a morbid condition has developed suddenly as a result of careful clinical observation, as the distinction of typhus from enteric fever; by the demonstration of constant and characteristic anatomical changes associated with it; and, more critically, by the discovery of a specific-causal factor, as the infecting organism of an infectious illness. Sometimes, however, it has been due to introduction of new methods of investigation, as the use of the electrocardiograph in that branch of medicine in which the founder of this lecture is a recognized authority.

More frequently the differentiation of separate diseases as seen through the centuries has been a long and slow process which has been retarded by failure to follow the straight path in the maze of clinical experience, by misinterpretation of observations, and particularly by failure to observe accurately and correlate clinical symptoms with morbid anatomy. And as most symptoms are disturbances of function, diagnosis has had in many cases to follow in the wake of physiology.

But the history of medicine reveals another and even more serious obstacle to progress which must be impressed on the student, or rather postgraduate, of to-day: it is too faithful submission to authority and failure to reason independently from facts observed. This will be evident in the subject I have selected to illustrate the evolution of clinical medicine. Many diseases might be chosen for this purpose, and the story of some might be more instructive, but, owing to the dramatic manifestations of epilepsy, its occurrence and views on its nature and pathology have been recorded since the dawn of history. Perhaps I have also been prompted to talk to you on the history of epilepsy by a subconscious memory of a statement by Oliver Wendell Holmes: "If I wished to show a student the difficulties of getting at truth from clinical experience I would give him the history of epilepsy to read."

An accurate definition of terms should be the first step in any discussion, and it is particularly necessary here, as history has recently repeated itself in a tendency to extend the connotation of the term "epilepsy": many, in fact, now speak of several types of convulsions and other episodic phenomena as belonging

to "the epilepsies." It will, however, suffice to state that here it is proposed to deal only with so-called idiopathic epilepsy—that is, a chronic disease without gross structural changes, characterized by periodic attacks of loss of consciousness with or without convulsions or other symptoms.

It is evident that in dealing with the early history of any morbid condition one must distinguish between the views of the layman and those of the physician. This is often difficult, as they may include in it different clinical entities—in fact, speak of different conditions. It is particularly so in the history of epilepsy, with which, till early in the nineteenth century, hysteria, vertigo, trances, the religious ecstatic states so common in the Middle Ages, and other conditions were often confused by both the profession and the people. But, on the whole, a fairly clear picture of genuine epilepsy is presented in early literature.

Views of the Greeks

Scientific medicine—that is, direct clinical observation and application of reason to the facts observed—came to birth in Greece about the end of the fifth century B.C. Some of the medical knowledge then possessed by the Greeks may have been derived from earlier Arabian and Egyptian physicians, but the empirical practice of the East was from this period largely replaced by attempts at a materialistic interpretation of the universe and of vital phenomena.

The earliest contribution to epilepsy that we possess is a treatise by Hippocrates or by a member of his school, *On the Sacred Disease*, written about the middle of the fifth century B.C. It contains an attack on the superstitions of the people, and probably of physicians too, who had regarded it as a disease of divine origin. It is therefore evident that epilepsy, or conditions confused with it, was recognized by previous generations. In the Hippocratic monograph it is insisted that all illnesses have natural or material causes and that epilepsy is no more sacred or divine than other diseases. It is not due to the wrath of the Gods, demoniac possession, or other extraneous influences. Divine and supernatural influences were denied, and anthropomorphic and religious theories of earlier philosophers and priests were replaced by a pathology that was the first step in scientific knowledge.

The clinical descriptions are excellent, and contain many observations that were overlooked during the next two thousand years. It was recognized that epilepsy rarely starts after the age of 20, that there is often a hereditary tendency, that its manifestations vary, that it sometimes ceases spontaneously, that attacks occur in sleep and particularly on waking, and that when associated with injury of one side of the head convulsions may be limited to the opposite side of the body. It was also observed that in chronic cases the brain may be abnormally moist—a fact well known now, as cerebrospinal fluid accumulates on its surface and between its convolutions when its tissue atrophies. Further, epilepsy was attributed to irritation of the brain by acid or sour substances—an interesting fact, as it is the first indication of localization in it of pathological processes.

* The first Price Lecture, delivered in the Queen's University, Belfast, on May 9, 1946.

2 JULY 6, 1946

school regarded epilepsy as a cerebral disease. It is hard for us to recall the views of the Greeks on the brain. Some years earlier Alcmaeon taught that the brain was the seat of consciousness; but this was not generally accepted by the philosophers up to the time of Hippocrates. For many subsequent years the nature and the seat of consciousness and mind occupied a dominant place in Greek philosophic discussions, largely to the exclusion of somatic functions. Intelligence, the passions, and sensibility were by various authors referred to the heart, liver, lungs, and other visceral organs. According to Hippocrates, however, the brain is the organ of the mind; it is by it we think and understand, see and hear. All intellectual and moral activities depend on it; it is the interpreter of intelligence, but intelligence is carried to it by air that circulates through the veins. If the veins are blocked by cold phlegm the patient becomes unconscious and an epileptic attack occurs.

The influence of the teaching of Hippocrates is obvious in Plato's hypothesis that epilepsy is due to a mixture of white phlegm and black bile which obstructs the circulation of air to the head. But Plato's dogma that it is necessary to avoid the confusion caused by evidence afforded by the senses and to determine truth by argument alone was largely responsible for failure in advance in the natural sciences during the following sixteen centuries. The influence of his teaching persisted, though in his later writings Aristotle emphasized the necessity for observation and the importance of determining concrete facts.

Aristotle attributed disease to morbid changes in the body, and refuted belief in magic and intervention of divine and demoniac agencies. Though there is no evidence that he studied anatomy or performed dissections, he repeatedly marshalled evidence to prove that the heart was the "sensorium commune"—the organ of sensation and intelligence—and that the only function of the brain was to cool and purify the blood, or rather the air or vapour that is conducted to it by the veins. He attributed epileptic seizures to these vapours being too condensed by the cold brain and therefore impeding the action of the heart when they return to it. These humoral theories favoured by Plato and Aristotle had for several centuries great influence on views on the pathogenesis of epilepsy.

Although Plato, Aristotle, and other Greek philosophers sought to explain illness of the body and often afflictions of the mind by somatic or material causes, not only was the application of scientific methods to the study of man neglected by their successors, but, as the fate of Socrates shows, denial of divine intervention in natural happenings was, as it also became in later years, a dangerous heresy. Even early in the eighteenth century Hippocrates was accused of atheism.

The Next Milestone

The work of Galen in the second century A.D. is the next milestone in the history of epilepsy. Galen was an anatomist as well as a first-rate clinical observer; he insisted that the brain is the organ of mind, of sensation, and of movement—not merely an inert mass or a kind of cold wet sponge which cooled the humours, as some of his predecessors believed. He published excellent descriptions of the clinical features of epilepsy, and insisted that it is always due to disorder of the brain, though in certain types the brain may be affected sympathetically by disease of other organs, as the stomach.

He was probably the first to describe local epilepsy, and observed that its clonic spasms may be sometimes arrested by tying a band round the limb in which they start. He observed, too, that when unilateral convulsions reach the head consciousness is generally lost. He assumed, however, that convulsions limited to one limb were due to an affection of peripheral nerves, those involving the whole body except the face to disturbance in the spinal cord, while those in which the face was also affected originated in the brain.

His view on the exciting cause of generalized convulsions was that the humour or principle on which sensation and motion depend, or by which the brain acts on, or is acted on by, the rest of the body, is elaborated in the anterior ventricles of the brain, passes through the third and fourth ventricles, and is thence distributed to the periphery. When this humour becomes too thick or viscid its circulation is impeded, and the

brain, which in its reaction he compared to the strings of a harp, is agitated and thus causes convulsions. On the other hand, accumulation of viscid humour in the substance of the brain produces changes in intelligence and temperament such as are common in epilepsy. It is interesting that he also attributed convulsions to excessive humidity, or, as we would say to-day, to hydration—a factor which has been again recognized only within recent years.

Areteaus of Cappadocia, who practised medicine a little later than Galen, also furnished excellent descriptions of epileptic phenomena, particularly of the initial stages or *aurae* of seizures. He also recorded post-epileptic paresis and anaesthesia, the mental disorders that occasionally follow attacks, and the dementia that frequently develops in chronic cases. He had apparently no doubt that seizures originate in the brain owing to disturbances in the circulation of animal spirits. As late surgeons, he found that merely opening the skull, or cauterizing the underlying brain, might arrest seizures for a time.

After the philosophic age of Greek culture search into the nature of things declined except in Rome, but as here learning and research were directed to more practical or material ends there is little new in the records which have come down to us on the nature of epilepsy. That it was common among the Latins is evident. They gave it the name "*morbis comitialis*," as their meetings in comitia were suspended when one of those present had a seizure, since this was attributed to demoniac possession or to a malign influence of a god, who by this means indicated his displeasure at the proceedings. In the first century B.C., however, Lucretius, who in his often-quoted verse gave an excellent and detailed description of an attack, attributed it to physical or rather humoral causes. At the onset the patient "Struck as with lightning by some keen disease, drops sudden," and, as the attack passes off, "The morbid cause declines, and the fermenting humours from the heart flow back."

The Old Superstitions

But the old superstitions still held sway. They were universally accepted by the people, and probably by the educated too, for, as Francis Bacon wrote, "In all superstitions wise men follow fools." It was so among the Hebrews, who were at that time under Roman rule; for both St. Matthew and St. Mark record the case of an epileptic boy, one of whose seizures occurred in the presence of Jesus, who according to St. Mark said, "Cast out the devil," or in St. Matthew's words, "the foul spirit." The characteristic abrupt cessation of the convulsions and the rapid recovery after a brief period of coma could obviously be explained by the hypothesis that the victim had been suddenly freed from a malign possession.

It is consequently not surprising that, later, demonology became a dogma of the Church and doubt a heresy. Its influence extended through the Dark Ages of the next 1,400 years. Independent thought and investigation were largely replaced by tradition and often suppressed. Belief in witchcraft and possession by demons was almost universal; the Church frowned on views discordant with precedent, and Medicine relied largely on authority, which, as Sir Thomas Browne wrote, has always been a "powerful enemy unto knowledge." In the thirteenth century St. Thomas Aquinas, and two centuries later Martin Luther, admitted the possibility of possession by evil spirits, and even in the sixteenth century epilepsy was spoken of as a "demon disease." The professional reputation of Chaucer's Doctor of Physik was based on his acquaintance with ancient Greek, Arabian, and Roman authorities and on his knowledge of the humoral pathology of Empedocles.

"He knew the cause of everich maladye,
Where it of hoot or cold, or moyste or dry,
And where they engendred and what humour."

Throughout the Middle Ages there were, so far as we know, only variations of ancient theories and little or no original research or speculation into the nature of epilepsy. Seizures were often confused with outbursts of hysteria and other conditions, while most still believed in demoniac possession; others held that the moon and the planets could influence the occurrence of fits. Relief was consequently sought in prayer and fasting, and in magic charms and rituals.

In the first half of the sixteenth century Jean Fernel, whose biological philosophy Sir Charles Sherrington has taken as the

text for his Gifford Lectures, *Man on his Nature*, recognized various types of epilepsy, emphasized its common hereditary tendency, attributed seizures to poisons or vapours irritating the brain, and produced pathological evidence which he thought confirmed this view. But he did not definitely exclude possession, for he recorded the case of a man who was regarded as an epileptic, but from the record was beyond reasonable doubt subject to hysterical seizures, in whom "a certain devil was found to be the cause of this ill." He protested against the prevalent use of charms as a means of warding off attacks, as carrying in writing the names of the three kings who came to worship the infant Christ.

A New Era in Neurology

A new era in neurology was introduced by Sir Thomas Willis (1621-75), whom Soury, the historian of neurology, compared in the vividness of his imagination, brilliancy of style, and profundity of thought to Shakespeare. Though known chiefly as an anatomist, Willis was also a pathologist who correlated symptoms of disease with structural lesions, and a physiologist who attempted to elucidate function by relating the functional capacity of the animal to the development of different portions of the brain. He recognized that the forebrain is not only the organ of mind and that by which sensory messages reach consciousness, but also the origin of nervous impulses, or as he, following his predecessors, wrote, of "animal spirits," which when distributed to lower levels of the nervous system excite movement. He compared these nervous discharges to explosions of gunpowder, and attributed epilepsy to excessive and irregular explosions which in predisposed persons spread through the nervous system. He also taught that epileptogenous discharges originate in grey matter—not in the meninges, white matter, or ventricles of the brain, as was previously believed.

But even Willis did not escape the weight of tradition, for he wrote: "As often as the Devil is permitted to affect miserable mortals he is not able to draw more cruel arrows from any other quiver, or to show miracles by any better witch than by assaults of this monstrous disease." He also described how an attack could be recognized as the work of witches.

A generation later Boerhaave, the celebrated Dutch physician, attempted to explain the symptoms of epilepsy and of other diseases in terms of the physiology of his time. He recognized that many causes may precipitate an attack in one predisposed to epilepsy, and emphasized the importance of injury of the head and neck at birth as a factor. In his view the essential cause of seizures was excessive irritation or abnormal irritability of the brain. At first he believed that the epileptic discharge starts in the white matter of the forebrain, but later decided it may originate in the medulla oblongata. Boerhaave also distinguished hysterical and simulated convulsions from epilepsy, and described an interesting outbreak of mass hysteria in an orphanage which he suppressed by applying, or threatening to apply, a red-hot iron to each of the patients. But even Boerhaave was not wholly free from the influence of tradition, for he appeared doubtful if it was safe to exclude the possibility of supernatural causes in all cases.

During the next century little was added to the knowledge of epilepsy—in fact, a series of experiments on animals diverted attention from the conclusions to which Willis had come. Haller and others found the cortex of animals inexcitable, but evoked convulsions from the brainstem, particularly from the medulla oblongata, which suggested that this was probably the seat of origin of epilepsy. Even in 1859 Schroeder van der Kolk stated that fits are due to abnormal excitability of the medulla—a view shared later by Kussmaul and Russell Reynolds. Nonetheless also postulated the existence of a convulsive centre in the pons, and even Hughlings Jackson believed, for a time at least, that some convulsions depend on discharging centres in the pons or medulla.

It is not surprising that even when it was recognized that epilepsy was a cerebral disorder most of the hypotheses on it immediately exciting cause of an attack were indefinite and vague. The Hippocratic school, as we have seen, believed they were due to excessive and viscid humour acting on the brain; others explained them by obstruction to the circulation of a vital humour in the heart or brain; later, chemical substances and peripheral irritation were evoked as probable factors. Henle

attributed seizures to disturbances in the cerebral circulation. Kussmaul and others to spasm of the cerebral vessels—a view that later was repeatedly revived. It will be observed that all these theories sought to explain seizures by extraneural factors; Willis alone placed the essential abnormality in the nervous elements of the cortex of the forebrain.

Treatment and measures to prevent the occurrence of seizures which were till this time commonly practised both by the people and by doctors illustrate the prevalent ignorance and uncertainty on the nature of the disease. Hippocrates recommended strict dieting, fasting, purgation, counter-irritation of the head, and sometimes blood-letting. When it was believed they were due to the powers of darkness, prayers, incantations, and charms were the only obvious means of treatment. Charms of great variety were used in many lands: silver rings and rings made from coffin nails were popular in England; carrying three bairs of a milk-white greyhound was recommended in Ireland. But most reliance was placed on religious and mystical rites; even in the middle of the eighteenth century a protest was made at depriving the Church of its privilege of curing fits by holy means. From earliest times various drugs were also employed, but none proved so efficient as to be generally used till Sir Charles Locock introduced bromides in 1857.

Modern Views on Epilepsy

This short review of the history of epilepsy brings us to modern times, when the discovery that the surface of the brain is excitable, and that excessive stimulation of the cortex is liable to produce local or general convulsions, provided what is now generally accepted as conclusive evidence that it is here seizures originate. More refined experimental methods and, during the past ten years, the recording of the electrical activity of the brain have confirmed this conclusion.

But clinical observation and the scientific application of analysis and reasoning to facts observed had not yet exhausted progress. This was above all owing to Hughlings Jackson, who in a series of papers from 1861 subjected all features of epilepsy to a keen and masterly analysis. Few diseases have been subjected to such an intensive and critical study, few conclusions have stood so well the test of time as those drawn from it. In a long series of papers Jackson dealt with all its symptoms, discussed their nature, and related them to disorders of specific functions of the brain. Jackson's name is most commonly associated with local convulsions, which, being the simplest subject for study, naturally attracted his attention; but this is only a minor contribution to his fame. Particularly significant now is his statement that a convulsion is due to "a sudden and excessive discharge of many nervous arrangements representing movements, at once or nearly together, because the cells of these arrangements have by some pathological process become highly unstable." This was indeed a prophetic forecast of the results of later methods of investigation.

Another eminent English physician, Sir William Gowers, whose clinical studies and vivid descriptions of the phenomena of epilepsy are unsurpassed, came to a somewhat similar conclusion. According to him an epileptic outburst is due to an unstable equilibrium of the brain that depends on the molecular constitution of nervous elements, which are therefore predisposed to sudden releases of energy apart from an adequate stimulus.

The important part in the teaching of Jackson and Gowers is that the primary and essential disorder lies in the nervous tissue of the cortex, although various other factors may increase their liability to discharge. Later studies have added little to our knowledge. Jackson, Gowers, and others exhausted the limits of clinical observation and analysis, and laboratory investigations have served only to demonstrate factors that predispose to seizures in those subject to them.

Electro-encephalography

But suddenly and unexpectedly, as often happens in other branches of knowledge too, a new means of investigation was discovered which brings us much further in our search into the mystery of epilepsy. In 1929 Hans Berger found that the electrical activity of the brain can be detected through the unopened skull and scalp and recorded when adequately amplified. This activity, which is now generally known as "brain waves,"

appears as variations in the action potentials of large groups of neurons which beat together in synchrony, but it is so feeble that to be made visible in tracings it must be magnified one to two million times. These waves may be modified by several factors, as the arrival of afferent impulses, the state of consciousness, and emotion. Normal waves are more or less regular, but their rate and amplitude vary in different regions of the brain, to some extent in different individuals, and even in the same individual under different conditions.

A few years after Berger's discovery it was found that during epileptic seizures the rhythm and voltage of the waves are grossly modified owing to large numbers of neurons discharging synchronously or simultaneously. Owing to this grouping of discharges they are larger and slower; it is as though the ripples on a calm sea were suddenly by a gale transformed into much larger waves more widely spaced or separated from each other. An epileptic discharge has, indeed, been figuratively described as a "brain storm." It has also been found that different patterns of irregularity are associated with different types of seizures, and that deviations from the normal may occur in an epileptic in interparoxysmal periods.

By many the electro-encephalograph has come to be regarded as a magic wand that can clear away any doubts there may be in the diagnosis of epilepsy. This attitude is certainly unjustified, and may unfortunately cause not only an error but also the personal and economic tragedy that wrongly stamping a person as an epileptic may lead to. Let us see what is the position electro-encephalography occupies to-day. In the first place it is no uncommon experience for the physician to find that separate reports on tracings of the brain waves of any individual are widely divergent or even contradictory: one recorder may report the tracings he has obtained as normal, another that they indicate beyond doubt epilepsy, while a third may interpret his tracings as doubtful but sufficient to suggest the possibility of epilepsy and thus excite the fears, anxiety, and uncertainty that are so disturbing to the patient and to his relatives. For here, as in other branches of medicine, the significance of tests that are new, mysterious, or classed as "scientific" outweigh to the layman the value of expert clinical experience.

The changes in the electro-encephalographic tracings during and immediately preceding a seizure are characteristic and can leave no doubt of its nature; but often these can be demonstrable only when recorded during an attack—then they merely supplement direct observation. Occasionally, however, they appear between seizures and can then be interpreted as due to larvate attacks that present no outward or visible sign. Such deviations from the normal are undoubtedly valuable, especially when an attack has been unobserved and when information conveyed by the patient or his friends may leave doubt of their nature.

But electro-encephalographic abnormalities of the type associated with epilepsy occur even in normal persons who never have had, and probably never will have, a seizure. Lennox, whose experience is unrivalled, estimates that 10% of the population, and an even larger proportion of relatives of epileptics, give such records, and he and others have seen undoubted epileptics in whom abnormal tracings have never been obtained even on repeated examinations.

Recently attention has been directed to less characteristic or non-specific abnormalities, which are more common in tracings from epileptics than from normal persons, but they are not pathognomonic, and indicate at the most only an epileptic tendency. Their value in diagnosis is also reduced by the fact that they occur in other conditions, particularly in the psychoses, psychoneuroses, and after head injuries.

Changes in the rhythm of the brain waves as revealed by the electro-encephalograph have not, therefore, the absolute value in diagnosis as has the demonstration of the causal organism of an infectious illness, the Widal test in enteric fever, the estimation of blood sugar in diabetes mellitus, or even electro-cardiographic tracings in revealing lesions of the conducting system of the heart. To quote Denis Williams, who has had extensive experience both in the use of electro-encephalography and in clinical neurology: "With expert clinical case-taking the electro-encephalograph is needed as a diagnostic aid in only a minority of patients suspected of having epilepsy"; and "There is an unfortunate tendency among some clinicians to

substitute a laboratory report for a careful history and examination." Jasper, who has worked extensively on the subject also writes: "The electro-encephalogram cannot be depended upon to give a certain diagnosis of clinical epilepsy without the aid of other data."

Future experience, research, and the adoption of new methods may add to the value of recording the electrical activity of the brain in epilepsy, but to-day we can only regard it as ancillary or supplementary to clinical investigation and experience. It may, however, produce evidence of what Lennox has called "dysrhythmia" of the cortex—a state that can be regarded as the essential basis of epilepsy, though the patient is not subject to fits or other epileptic symptoms. It also frequently serves to identify the site of pathological changes in the forebrain whether associated with epileptic phenomena or not, and it has thrown light on the nature of the epileptic discharge. Electro-encephalography has done little more than confirm the hypothesis of the cause of epileptic convulsions formulated as result of his clinical studies by Hughlings Jackson more than 70 years ago, but it has made possible the visible recording of these excessive discharges.

Conclusion

Here our short sketch of the long history of epilepsy must end. To-morrow may throw new light on the abnormality of function that constitute liability to seizures and may perhaps bring new therapeutic measures for controlling this liability, but we can now inquire what light this history throws on the evolution of clinical knowledge, for, unless it conveys to us lessons from the past for the use of the present and the future, no matter how interesting history may be it remains barren.

It is obvious that the first step must be differentiation of each disease by clinical methods which mark out the features that distinguish it and make it possible to define it as a clinical entity. The next step is determination of the organ or disorder of which is responsible for the appearance of these clinical symptoms. Then comes recognition of the manner in which the functions of this organ are disordered, whether they are associated or not with structural disease—in other words, the interpretation of symptoms in terms of physiology. But in many pathological conditions clinical investigation alone cannot succeed in unravelling all the problems of disease; it must count on the assistance of laboratory and other ancillary methods that may throw light on the nature of the disorder and on the aetiological factors responsible for it.

Finally, the history of epilepsy emphasizes the importance of adequate clinical study of each disease, no matter how valuable laboratory methods may be, in order to make possible the synthesis and integration of information obtained from its sources and its relation to the patient as a whole; for the patient must ever be looked upon as a conglomerate of many more or less independent parts, but as a living adapted individual.

The history of epilepsy is particularly valuable for the student—and most of us remain students, though perhaps less objective and less receptive to new ideas as age advances—it shows that one of the most potent obstacles to the advancement of knowledge is reliance on authority and subordination of accurate observation and careful analysis in terms of function of the facts observed.

The Canadian Tuberculosis Association in its *Bulletin* for March, 1946, says that two of the great stumbling-blocks to effective control of tuberculosis have been lack of sanatorium beds and unsatisfactory arrangements to defray the cost of treatment. Steps have been taken during the past few years towards solving these problems. If present plans go through 3,000 additional treatment beds are likely to be available this year. Four provinces have already instituted free treatment for all their tuberculous sick. These are Saskatchewan, Alberta, Manitoba, and New Brunswick. Nova Scotia and Quebec have announced their intention to make similar arrangements at an early date. Meanwhile the educational programme has been intensified. Surveys have stimulated public interest, and they have provided valuable object-lessons in how much unsuspected tuberculosis there is likely to be in the general population. Another encouraging feature is the growing public interest in rehabilitation. During 1944 Canada's death rate from tuberculosis fell to its lowest point in history, namely, 47.7 per 100,000 of the population. Preliminary reports indicate a further reduction last year.

TYPHUS: EXPERIENCES IN THE CENTRAL MEDITERRANEAN FORCE

BY

M.R.C.S., L.R.C.P., D.P.H.

Colonel, Late R.A.M.C.; Late Senior Hygiene Officer, Allied
Armies in Italy

PART II

TYPHUS IN ITALY AND THE BALKANS

No information could be obtained about the presence of typhus in Italy prior to the Allied occupation. It was known that there had been outbreaks in the Balkans and on the Russian front (Don-Donetz regions). The fact that Italian soldiers returning to Italy from these fronts, as well as from Tunisia, might have brought the disease with them was appreciated. Subsequent events proved this supposition to be true. It was not, however, until some little time after the occupation of Naples that any accurate details were unearthed. Naples was occupied by the Fifth Army in October, 1943, and between November, 1943, and March, 1944, a sharp outbreak of typhus occurred in the city and the surrounding districts. Much has already been written about this epidemic in both the lay and the medical press. The main facts, with special reference to the British Army control measures, are given here. They are condensed from a report submitted by me to the War Office in March, 1944.

The Naples Outbreak

During the early days of the Allied occupation of Naples the general disruption of normal civil affairs made it almost impossible to obtain any accurate epidemiological data. The medical services were completely disorganized; there was little general practice and the public health service was barely functioning. As a result no accurate picture could be obtained as to the incidence of infectious disease. The city had suffered very severe damage. The gas, electricity, water, and sewage systems were out of action, and between 20,000 and 30,000 people lived more or less permanently in air-raid shelters. The people were apathetic and depressed. Lousiness was prevalent, especially in the hospitals and prisons. It was clear that these factors, operating in a malnourished unwashed populace of nearly a million, were ideal for the occurrence and rapid dissemination of infectious diseases. The main risk appeared to be that of an epidemic of the typhoid group. By good fortune this did not materialize in Naples, although severe epidemics arose in other towns.

This appeared to be unlikely, and later the following facts were elicited. It is hard to explain why this important information was at first withheld:

In July there were 12 cases among Serbian prisoners housed in Naples. Between that time and Nov. 20, cases occurred, chiefly among shelter inhabitants and in the large prisoner-of-war hospital. Earlier in the year a small outbreak occurred at Aversa, six miles from Naples. It had been the practice to quarantine soldiers returning from the Russian front at Trieste. A few military cases infected in Tunisia had appeared in different parts of Italy. Few details as to the action taken to prevent the disease spreading could be given us.

It was not until many weeks later that a full account of previous cases was obtained. This was contained in correspondence between the Naples civil authority and the Minister of the Interior, Rome, and the German Military Command. It may be summarized:

In March, a case in a town 15 miles from Naples; in April, 3 cases in soldiers returning from Russia; early in May, 6 cases outside Naples, including 4 children; in July, a civilian who had used a public bath-house in Naples frequented by soldiers returned home infested, contracted typhus, and died. The porter at the baths was next affected. New foci appeared in August in Naples prisons. Cases then occurred in a porter at the jail, a shelter warden, and a policeman. Six inmates of one prison died of typhus. Many "contact" prisoners escaped and could not be traced. The disease appeared in another town outside Naples, and there a quarantine was imposed. It was stated that the epidemic had been mild but that disinfection of contacts and cleansing of the jail were carried out; and, finally, "measures were taken in the city to get rid of body lice, but this was too difficult to control owing to the congestion of people living in the shelters." Between July and November there were 60 cases in the Naples area; there was also an outbreak at Forlì, in Northern Italy. Later information from another source stated that 70 cases occurred in various parts of Italy in troops from Russia.

Initial Action Taken.—Two responsible Italian physicians were appointed to carry out an inquiry and furnish daily reports. A committee was established consisting of representatives of the medical services of the Allied Forces, A.M.G., and Italian civil and military medical officers. Arrangements were made for the immediate putting into operation of the civilian disinfecting centre and for the delousing of hospital inmates. A meeting of Naples practitioners was called and the position explained to them. Daily notification of new cases and the preparation of spot maps were arranged for. The services of hygiene personnel were made available for assistance in disinfection and in the construction of showers and disinfestors. Malaria Control Units were also brought into the city for the purpose. Insecticide powder was asked for urgently, together with supplies of soap. Schemes were drawn up for controlling movement of the civilian population, and immediate disinfection and closure of the shelters was demanded. The importance of searching for and notifying all cases and dealing with contacts was emphasized.

The appropriate military authorities were at once informed of the danger to Allied troops, and formations were instructed to submit schemes to be put into operation in case of local necessity.

Progress of the Epidemic

Up to the end of the third week in December, 1943, the number of cases showed a slight but nevertheless significant increase: Nov. 16-23, 18; Nov. 24-30, 18; Dec. 1-7, 22; Dec. 8-14, 45; Dec. 15-22, 36. But between Dec. 22 and 28 a total of 138 cases were recorded. Drs. Soper and Davis, of the Rockefeller Foundation, arrived in Naples early in December. A scheme for case-searching (past and present cases) and the treatment of contacts with insecticide powder was put into operation about the middle of the month. The American Army insecticide powder containing pyrethrum was used, being applied mechanically by means of dust-guns. Every available contact in the family and outside, together with everyone in the building or block of buildings, was dealt with. A dusting centre was opened in a room in the house to which persons living in the neighbourhood could come. Up to 200 persons per case were dusted in this way. This method of application of insecticide powder (NYL, A.L.63, or D.D.T.) by means of dust-guns has particular advantages over the old-fashioned method of hand-dusting of the underclothing. It can be done without removal of the clothes and large numbers of people can be dealt with quickly and efficiently. The powder is forced up the sleeves so that it reaches the axillae, down the front and back of the neck inside the shirt, and inside the

TYPHUS
NAPLES 1943-1944

Every effort was made to obtain notification figures, a variety of sources being explored. In November there were rumours that typhus cases were appearing in the city. The word *tifo* is used rather loosely for both typhus and typhoid; a searching investigation was therefore demanded. On Nov. 24 the Regional Public Health Officer, A.M.G., who had been asked for further details, reported that the cases were true typhus. A conference was called by us on the following day, at which British and American hygiene officers and civilian public health doctors took part. At this meeting it was said initially that these were the first cases in Naples since 1935.

trousers to the pubic region. The hair is also dusted. Towards the end of the month public dusting stations were open in the city, and with the advent of the Typhus Commission these were quickly increased in number. Centres were also established at the railway stations and hospitals, at ferry embarkation points, and in refugee camps. The Italian staffs of these included doctors, nurses, and Red Cross workers. All were paid. Trained squads worked in the shelters, visiting each one periodically. No compulsion was placed on the populace to submit to this form of disinfestation, but its availability was made known through the medium of doctors, priests, and the Press. It was found that all were eager to be rendered louse-free, partly from their fear of typhus, but more probably because it gave them a freedom from body irritation which they had not known for many months. The efficacy of this mode of disinfestation needs no better testimony than this. The daily number of persons treated rose to 60,000, and by the end of February, 1944, 2,250,000 people had been dealt with. This figure does not include the civilians employed by the British and U.S. Forces. 30,000 civilians in British Army employ were dusted with A.L.63 at fortnightly intervals. This was done by Malaria Control Units.

The U.S. Typhus Commission

This organization, under the direction of Brig-Gen. Fox, arrived in December, 1943, and began operations early in January, 1944. It comprised sections for case-finding, contact delousing, mass delousing, inoculation, and refugee delousing, together with a "flying squad" for investigating new outbreaks, and a Central Advisory and Control Branch. D.D.T. powder was made available in large quantities and a 10% mixture in talc was used exclusively for civilian dusting. It was not until late in December that it had first been obtained. During this preliminary period only 10% of the total dustings were carried out with D.D.T. All the dusting was done by means of dust-guns. R.A.M.C. officers, 17 in number, loaned from general hospitals, assisted the Typhus Commission.

Administrative Control

A Typhus Control Board was set up by authority of Sir Brian Robertson, the Chief Administrative Officer of the Allied Central Mediterranean Forces, under the chairmanship of Brig. Galloway, the D.D.M.S. The members consisted of Brig-Gen. Fox, U.S. Typhus Commission; senior administrative medical officers of the British and American Armies, and of the Allied Commission and the Allied Military Government; and myself. At its meetings civilian and military control measures were co-ordinated, and difficulties in such matters as transport, personnel, and equipment sorted out. It fulfilled a most valuable function.

The local committee, inaugurated in November, continued to meet weekly. Allied Navy, Army, and Air Force officers attended, as well as Italian military and civil doctors. The Regional Public Health Officer, Col. Crichton, acted as chairman. These meetings were very successful, and they enabled problems to be solved which could not otherwise have been tackled. (See also *Journal*, June 29, p. 996.)

Frequent meetings of general practitioners were arranged by A.M.G. The doctors and their families and members of the nursing profession were offered immunization. The response to this was disappointing, and inoculation proceeded very slowly—the result of a belief that untoward results often followed its administration. Such an attitude of mind, which had its counterpart in Algeria, is inexplicable.

Further Control Measures

Cinemas and public places of amusement were closed. The reopening of schools was agreed to, for children could be dusted there and propaganda fostered.

When railroad travel restarted no civilians were allowed on the platforms at Naples without being dusted. The control of road traffic from the city was supervised, but, although civilians were required to furnish proof of having been dusted before being issued with passes, there was a very considerable leakage. This was fostered by a black market in disinfestation certificates. The problem of refugees from forward areas promised to be a serious one. A few scattered cases occurred in these areas, but contacts were very efficiently dealt with by field hygiene sections and divisional

medical officers. Steam disinfestation was used at first, and later insecticide powder (A.L.63 and MYL). Camps were eventually established where all refugees were deloused before dispersal. Large numbers of these refugees passing through Naples were treated with D.D.T. by Typhus Commission teams. Five tons of A.L.63 powder were released from our stocks to A.M.G. for refugee use in the Army areas, and portable disinfestors were lent.

British Army Control Measures

These were based on early propaganda by means of lectures, films, posters, and newspaper articles. The streets of Naples were plastered with signs prepared and erected by the hygiene sections. Routine instructions were issued regarding baths, A.L.63 powder, etc.

Naples was the principal Allied port in Italy. At this critical stage of the campaign, with the landing at Anzio imminent, the port had to be kept working at full capacity. It was also an important leave centre for fighting troops, the Allied Navies, and the Mercantile Marine. As a port of disembarkation and a railway terminus, thousands of troops passed through it in transit. To have placed the city entirely out of bounds would have been a serious matter, and this step was deferred as long as possible. Troops were forbidden entry to certain parts of the town and the use of public vehicles, cinemas, and restaurants. As the epidemic increased, this decision had to be reconsidered, for in the narrow streets and alleys with which the city abounded it was impossible to avoid rubbing shoulders with civilians. Prostitution was rife, and rigid policing of the prohibited zones was a difficult matter. So on Jan. 9, 1944 it was recommended that Naples be placed out of bounds to all Allied Forces other than those on essential duty;—this was agreed to. All Allied seamen were included in the order, but in spite of the hardship this imposed on them it was safer to confine them to the dock area than to allow them to run the risk of getting infected and carrying the disease to other parts of the world.

The British Army inoculation state, at first low, was gradually raised as Cox's vaccine became available. Brig-Gen. Fox was instrumental in obtaining supplies from America for our use. The work of hygiene sections in constructing baths and disinfestors has already been referred to, as has the part played by malaria control units who formed the mobile teams. We employed Italian tinsmiths to make dust-guns. These were afterwards manufactured at Army workshops. Power-gun were experimented with, and were used by the mobile teams. Civilians employed by the British Army were dusted every two days, and a selected number of these were given injections of the vaccine of Durand and Giroud. Many cases occurred in the Italian Navy and Army during the early days, when the degree of infestation in barracks and hospitals was high. They were supplied with dust-guns, A.L.63 powder, and vaccine. Leave of Italian troops to Naples was cancelled, and those departing from the area were dusted and quarantined. Few Italian Service cases of typhus occurred in 1944—in marked contrast to the incidence at the end of 1943.

British Army Cases

One British soldier was infected in Naples. The victim was a deserter. He was apprehended after hiding in the slum quarter, and was heavily infested when caught. Two other cases of typhus occurred, but the place of infection was probably North Africa. So far as is known, there were no cases among the 25,000 to 30,000 civilians employed regularly by the British Army. Many casual workers were attacked

Hospital Arrangements

The regular infectious disease hospital was not being used as such in November. It was bomb-damaged, and was in military occupation. The alternative accommodation was even less suitable, and after some difficulty the original premises were released and partially repaired. Heating, lighting, kitchen, and

Road Sign in Naples (62 Field Hygiene Section)

thing arrangements were sadly deficient, as a result of which the feeding and preliminary cleansing of patients was imperfect. The long delay between the reception of the sick and their admission to the wards was a particularly unsatisfactory feature. Improvement, which was only gradual, necessitated instant pressure and much material assistance before it came to being. A research team under Lieut.-Col. Stuart-Harris, A.M.C., took over 50 beds. Twelve British Army nurses, who volunteered for this duty, worked in these wards; a detachment of the Friends Ambulance Unit also assisted. There were many difficulties and no few risks attached to this work. There was a shortage of civil ambulances. This was one reason, but not the most important reason, for the delay in admitting patients to hospital. American and British ambulances were loaned, and even taxi-cabs were utilized. Extra accommodation was soon required, and a building was released from military requisition for housing convalescent cases. The dietary of these patients was quite inadequate. We obtained supplies of meat from our own stocks to augment their meagre rations.

Subsequent Course of the Epidemic

By Jan. 8 cases had increased to 65 in a day. These were all distributed throughout the city. The outlook was black. There was nothing to suggest that this epidemic would not be the way of all previous winter typhus outbreaks and increase in intensity. But this was not so. During the week that followed notifications fell suddenly from 340 to half that number. This level was maintained for each of the ensuing three weeks, when a further sharp drop was recorded. Thereafter the epidemic gradually petered out. About the middle of January places outside Naples began to be affected. Each week until the end of March there were about 30 cases; this secondary focus persisted after the primary one had been extinguished.

Clinical Notes

The disease was not quite as severe in type as that encountered in North Africa. According to Stuart-Harris it resembled the Polish outbreaks of pre-war years. It is probable that it had its origins in Eastern Europe, and not in North Africa. There was a high proportion of cases among children. In these the infection ran a mild course. This to a lesser extent was true of young adults, but in this group the pyrexia persisted for a long time. The general mortality figure was 15%: half the patients over the age of 50 died. The long delays in reheated reception-rooms, before reaching the wards, tended to increase the death rate. Early admission to hospital was not the rule—due not so much to transport deficiencies as to concealment and failure to notify, for which not only the relatives but the civilian practitioners were sometimes to blame. Cases were seldom seen before the fifth or sixth day of illness. The rashes observed were typical, but were not a constant feature. The Weil-Felix reaction was positive as early as the fifth day, and the British research workers were able to recover rickettsiae from the blood in early cases, in a large proportion of patients, using guinea-pigs.

Factors Influencing the Cutting Short of the Outbreak

It was clear after Jan. 9 that the epidemic was under control. Assuming an incubation period of 12 days, and taking into account the delay in notification until the fifth or sixth day of illness, the measures responsible must have been operating 8 days previously—i.e., just before Dec. 23. At this time there was intensive case-searching and mechanical dusting with the U.S. Army pyrethrum powder (MYL) of contacts and persons living near. Until early in January, D.D.T. powder was used in about a tenth of the total dustings only. It was not used at all until the end of this period, by which time there were 6,000 dustings a day. Hospitals, jails, railway stations, and shelters as well as contacts were dealt with. By Dec. 27 all the shelter inhabitants were being dusted every ten days. This work was under the direction of the Rockefeller Foundation team. The initial defeat of the outbreak was brought about by the energetic pursuit of the principles mentioned above—viz., a search for cases and contacts and prophylactic mechanical dusting with an efficient insecticide powder. The armies and their civilian workers were protected with either

MYL or A.L.63 powder, which did not at this time contain D.D.T. Only two or three cases of typhus occurred in this large group. Casual employees, whose number was probably equal to the regular ones, produced many cases. They were not under close supervision, and their periodic dusting could not be ensured.

D.D.T. was brought into use on a large scale early in January, and mass civilian dusting was intensified, together with other preventive measures. An enormous decrease in the louse population of Naples followed. Thus the epidemic, already defeated, was given its *coup de grâce*, and all risks of a flare-up were prevented.

Civilian inoculation played only a minor part in the cessation of the epidemic. By the end of April 60,000 out of a population of more than a million had been inoculated, but in December the number was negligible. The British Forces' inoculation state was at a seriously low level early in December: this was not more than 70% at that time. Our Merchant Navy and the Italian armed Forces were totally unprotected until later. From the evidence available, in Algeria as well as Italy, it would appear that inoculation with the killed vaccines does not necessarily protect against infection; its value lies rather in the reduction of the mortality rate.

The economic situation did not improve during the early months of 1945. Indeed, it deteriorated very much at times. In January the Regional Public Health Officer called attention repeatedly to the gravity of the food situation. There were marked deficiencies in the dietary: the protein content was particularly low. The black market flourished, and fantastic prices were paid for such things as tinned meat. None but the wealthy could procure these articles. Poor-class patients admitted to the typhus hospital were all undernourished, unwashed, and very badly clothed, but few were actually near starvation. Regular washing and changing of underclothes was out of the question, owing to the lack of soap and fuel. The number of permanent shelter-dwellers, of which there were about 20,000, fell but little during January. The need for finding other accommodation for these unfortunate people was stressed time and again. A civilian committee detailed to deal with the problem of this large reservoir of infection did little to grapple with it for some time. These people lived under primitive conditions in the labyrinth of ancient caves and tunnels deep below the city. This did not, however, prove to be entirely disadvantageous, for they were always available for supervision and periodic mechanical dusting.

The quenching of the epidemic cannot, therefore, be associated with any improvement in the nutrition or the social and economic condition of the Neapolitans.

General measures such as the prohibition of meetings, concerts, and the use of cinemas, and the search for cases and their removal to hospital, did much to localize points of infection. The Church, Press, and medical profession were used extensively for propaganda. The response to this was variable. The least efficient part of the organization was the control of movement into and away from the city, which was found to be difficult to supervise: there were very many roads to police—military congestion on these roads made it no easy matter to establish check-points; it was unfair to curtail the amount of farm produce brought in daily from the country districts; and there were civil police deficiencies. Forged "dusting certificates" have already been referred to. In spite of these obstacles this aspect of control should have received greater attention. This leakage was responsible for some 300 cases in nearly 50 separate communities outside Naples. Each had to be dealt with individually. Shortage of transport for the "flying squads" of the Typhus Commission meant unnecessary delay in this work. We made repeated representations for the loan of Army transport, but little was done. Since most travellers leaving Naples by train were thoroughly dusted, secondary cases rarely appeared in remote parts of Italy.

Lessons Learned in Naples

- (a) An epidemic of typhus can be terminated in the winter months even in a city where conditions are most favourable for its spread.
- (b) Intensive searching for cases and the disinfection of contacts and the general public were the most important measures adopted. Other public health measures must not be overlooked—in particular, the control of movement.

(c) An army can live and work in a typhus-ridden city with almost complete impunity, provided discipline is maintained and prophylactic dusting is carried out efficiently and regularly.

(d) The principle of dusting fully clothed people, using hand- or power-dusting apparatus, is a notable advance on former methods of dealing with lousiness in a community. Its use in the Army allows cumbersome steam and hot-air apparatus to be done away with.

(e) Any efficient insecticide powder applied in this way will be successful in guarding against infestation and reinfestation, as well as in treating it. The method is without equal for dealing quickly with large groups of people. Its worth was proved at a later date in disinfesting immense numbers of prisoners and refugees.

(f) D.D.T. is a new weapon in preventive medicine. It does not kill lice quickly, but it is non-irritant and persistent, having a residual action which prevents reinfestation. It is particularly valuable where people are not under strict discipline and washing and laundry arrangements are defective.

(g) Civilian inoculation played no part of importance in the extinction of the epidemic. The British Army, which escaped with one case, contained a large number of uninoculated troops at the peak stages.

(h) A well-equipped organization is essential. Adequate staff, equipment, and transport must be available. In Naples this was obtained by pooling Allied resources; but some valuable time was lost, and there were marked deficiencies in some directions, which might have proved a serious handicap.

(i) In conclusion, it should be stated that there was the closest and most amicable co-operation between British and American medical officers of the two Armies, the U.S. Typhus Commission, the Rockefeller Foundation, the Allied Commission, and the A.M.G. Senior Italian civil and military doctors also gave full support. This unity must occupy a high place among the factors which contributed to success.

YUGOSLAVIA

We had three foci of typhus infection to contend with in Italy—Naples, North Africa, and Yugoslavia. Large numbers of sick and wounded partisans and refugees were evacuated to Southern Italy from the Balkans. The care of these was a British responsibility. It was known that typhus was epidemic in the Balkans, and measures had to be taken to prevent its being carried to Italy by these evacuees.

During the spring and summer of 1943 about one case of typhus arrived in Italy each week with the sick and wounded. Many casualties came by air; these were dusted in the aircraft. Others arrived by sea. Dusting stations were set up on the island of Vis, the place of embarkation. Information was received that typhus was rife among Italian units left in the Balkans. Supplies of the vaccine of Durand and Giroud, together with dust-guns and A.L.63 powder, were sent them by air. The refugees were all bathed and disinfested. Steam disinfestors were used at first; subsequently mechanical dusting was employed.

It was significant that Yugoslav cases continued throughout the summer. During the following year there were many localized epidemics. A British medical officer with the Partisan forces informed me that there was an epidemic at Sarajevo. All the hospital inmates were lousy. Dust-guns and large supplies of A.L.63 powder were sent to this area. There were also cases of typhus in Greece. After the reoccupation of the country by the British Army, large-scale dusting of refugees was carried out immediately by the hygiene sections. The disease did not become epidemic there.

Although many cases of typhus from the Balkan countries were treated in hospital in Italy, no contact cases occurred either in the Allied Armies or among civilians there. The meticulous care with which both the Army hygiene staffs and the R.A.F. dealt with this problem was thus well repaid.

Summary

An account is given of civilian typhus problems in North Africa, Italy, and the Balkans. Reasons for the comparative immunity from attack enjoyed by the Allied troops are discussed.

In Algeria a severe and widespread epidemic was brought under control by concentrating on mass inoculation of the Arabs with a living vaccine, despite the fact that the infestation rate remained high. In Italy a sharp localized outbreak was terminated in the winter. Inoculation played no part in this. The most important single measure responsible was the mass delousing of contacts and

the general population, using insecticide powders applied mechanically. The use of D.D.T. powder on a large scale showed it to be a valuable insecticide, with a marked residual effect. No to effects followed its use in powder form.

The energies directed towards the prevention of typhus were repaid by results. An important reason for success was co-operation given by the troops themselves—officers and men alike. By contrast, the efforts made to prevent malaria, dysentery, typhus, venereal disease, etc., were far less successful, although Army hygienists attacked these problems with no less vigour. But support given by the non-medical branches of the Army was as whole-hearted. The solution is to be sought in the greater education of all ranks of the Army in the principles of preventive medicine, so that they fully appreciate how important a factor it is in the successful conduct of a military campaign.

I wish to acknowledge my indebtedness to Brig. Galloway D.D.M.S., A.C.M.F., and to the hygiene officers who worked with me in North Africa and Italy, for the support and co-operation they gave, and the zeal with which they tackled a difficult problem. The following gentlemen, who all played a prominent part in the event at Naples, supplied me with a great deal of information; I have drawn freely from their reports in the preparation of the second part of this paper: Brig.-Gen. Fox and Col. Bishop, U.S. Medical Corps, U.S. Typhus Commission; Dr. Soper, Rockefeller Foundation; Col. Crichton, I.M.S., A.M.G.; Col. Williams, U.S. Medical Corps, Allied Commission. Dr. Grenouilleau, Chief Public Health Officer, Algeria, furnished me with full details of the Algerian epidemic. These have been used extensively in this paper. My thanks are due to him for his unstinted advice and assistance during the critical early days in Algeria.

PENICILLIN IN TREATMENT OF SEVERE DIPHThERIA

BY

RICHARD J. DODDS, M.B., B.S.

Resident Medical Officer, Sheriff Hill Isolation Hospital, Gateshead

Since 1936 Gateshead has had an epidemic of unusually virulent diphtheria with a high proportion of "gravis" type infection. Many cases of which have appeared resistant to antitoxin. There have been 2,911 cases with 147 deaths, giving a case mortality rate of 5% over the years 1936 to 1945 (J. Gray, 1936-45). The severer forms of the disease—namely, the pharyngeal and nasopharyngeal varieties—have had an associated case mortality rate of 14%. The earliest opportunity was therefore taken in 1945 to try the effect of penicillin, given in addition to the customary therapeutic dosage of diphtheria antitoxin, on severe cases of diphtheria. The results to date are embodied in this paper.

Few reports have so far appeared in the medical literature on the use of penicillin in the treatment of diphtheria. Symo (1945) described a case of an immunized boy with a severe mixed infection (*C. diphtheriae* and haemolytic streptococci) who made a dramatic recovery following the administration of antitoxin and penicillin. Archer (1945) reported a similar favourable result in a woman with triple infection (diphtheria streptococci, and Vincent's angina). Recently Christie at Preston (1946) gave details of two cases of severe diphtheria treated by a combination of serum, intramuscular penicillin and local penicillin spray; the first patient did very well, but the second died in spite of prolonged treatment.

To carry out an adequately controlled investigation on the value of penicillin in the treatment of diphtheria it would be necessary to analyse the results obtained in three fully comparable groups: (I) cases treated with diphtheria antitoxin alone; (II) cases treated with penicillin alone; (III) cases treated with a combination of antitoxin and penicillin. The last group is included to determine whether penicillin and diphtheria antitoxin exert on each other any synergistic action.

On the preliminary results obtained with Group III cases—that is, those treated with antitoxin and penicillin—it would seem exceedingly unwise to treat severe cases of diphtheria with penicillin only; and, as the results obtainable from the treatment of milder cases with penicillin alone would be of no value as a comparison, Group II has been discarded—f

TABLE I.—Cases Treated with Penicillin and Antitoxin

Case	Age and Sex	Day of Disease on Admission	Clinical Condition	Antitoxin Dosage and No. of Occasions Injections given	Penicillin When first given. Duration of Treatment. Total given	Days after Admission till Throat Clean	Complications	Days in Hospital	Remarks
1	19 F	1st	O.A.: Mod. tonsillar diphtheria. 20,000 u. D.A.T. given. Membrane spread for 48 hours till severe pharyngeal in type, with faucial oedema and bullneck	170,000 u. 3	3rd D.O.D. 48 hours 400,000 u.	5	Persistent albuminuria	35	Gross oedema of fauces and bullneck; very toxic and disorientated. Penicillin on 3rd day; condition improved rapidly. Throat clean 72 hours later
2	43 F	3rd	Severe nasopharyngeal, with profuse rhinorrhoea and bullneck. Type, "gravis"	120,000 u. 2	3rd D.O.D. 48 hours 400,000 u.	—	Persistent albuminuria. Myocarditis; tachycardia. Vomiting; Death	13	Rapid reduction in bullneck and clearance of rhinorrhoea after penicillin. Cardiac sickness 7th day. Died 16th D.O.D.
3	16 M	2nd	Severe nasopharyngeal. Oedema of fauces and uvula. Bullneck	100,000 u. 1	3rd D.O.D. 48 hours 378,000 u.	5	Persistent albuminuria	62	Swab not negative until 59th D.O.D. Good recovery
4	6 F	2nd	Severe pharyngeal. Bullneck. Type, "gravis"	100,000 u. 1	3rd D.O.D. 48 hours 360,000 u.	5	Nil	57	Good recovery
5	6 F	2nd	Moderate nasopharyngeal. Bullneck. Type, "non-gravis"	70,000 u. 1	2nd D.O.D. 48 hours 360,000 u.	4	Nil	43	Good recovery
6	13 F	2nd	Severe nasopharyngeal, with very gross oedema of fauces, rhinorrhoea, bullneck, and albuminuria O.A.	150,000 u. 2	2nd D.O.D. 4 days 720,000 u.	6	Albuminuria. Palatal paresis. Myocarditis; extrasystoles	84	Spread of gelatinous membrane for 48 hours A.A. Very restless and toxic for 5 days
7	16 F	5th	Severe pharyngeal. Marked faucial oedema and early periaadenitis	100,000 u. 1	5th D.O.D. 48 hours 400,000 u.	6	Transient albuminuria. Palatal paresis. Mild peripheral neuritis	53	A well-established case on admission
8	19 F	7th	Severe nasopharyngeal. Gross "gelatinous" faucial oedema (and uvula). Profuse post-nasal discharge. Very toxic. Type, "gravis"	90,000 u. 1	7th D.O.D. 5 days 560,000 u.	8	Myocarditis; extrasystoles	61	Very ill, and at times disorientated for 5 days A.A. Collapsed on day A.A.; pulse soft and irregular; "cardiac collapse." Responded to restoratives; no complications afterwards
9	25 F	3rd	Severe pharyngeal. Thick membrane with spreading edge extending beyond molar teeth. Bullneck	100,000 u. 1	3rd D.O.D. 3 days 540,000 u.	8	Albuminuria. External and internal ocular palsies. Palatal paresis. Peripheral neuritis	77	One fainting attack during convalescence. No signs in C.V.S.
10	10 F	? 1st	Severe pharyngeal. Moderate faucial oedema. Bullneck	110,000 u. 2	2nd D.O.D. 4 days 400,000 u.	7	Nil	43	Considerable spread of membrane on day A.A. One prophylactic inoculation against diphtheria B.A.
11	20 M	2nd	Moderate nasopharyngeal. Periaadenitis	180,000 u. 4	3rd D.O.D. 4 days 480,000 u.	9	Nil	41	Membrane spread for 3 days A.A. Toxic and disorientated for 1 week; then made an uneven recovery
12	14 F	3rd	Severe pharyngeal. Early periaadenitis	90,000 u. 2	4th D.O.D. 48 hours 400,000 u.	5	Secondary tonsillitis	34	Spread of membrane 24 hours A.A.
13	20 F	4th	Severe nasopharyngeal. Fauces and uvula very oedematous. Mild periaadenitis	100,000 u. 1	4th D.O.D. 4 days 400,000 u.	6	Nil	34	Very toxic O.A.

TABLE II.—Cases Treated with Antitoxin Only

Case	Age and Sex	Day of Disease on Admission	Clinical Condition	Antitoxin Dosage and No. of Occasions Injections given	Days after Admission till Throat Clean	Complications	Days in Hospital	Remarks
1	12 M	2nd	Severe nasopharyngeal. Very extensive membrane and moderate faucial oedema. Early bullneck	100,000 u. (40,000 I.V.) 1	7	Persistent albuminuria. Palatal paresis. Myocarditis; extrasystoles	75	Lethargic and ill for 4 weeks A.A.
2	6 F	4th	Severe pharyngeal. Membrane on to pillars of fauces only; no oedema. Moderate bullneck	110,000 u. 2	6	Persistent albuminuria. Palatal paresis. External ocular paresis	34	
3	19 F	3rd	Severe pharyngeal. Spread of membrane on one side of soft palate. Moderate oedema. Severe adenitis	90,000 u. 1	4	Transient albuminuria	33	Good recovery
4	25 M	3rd	Moderate nasopharyngeal. Extensive membrane but little faucial oedema. Early bullneck	100,000 u. 1	3	Nil	37	Attack of abdominal pain of uncertain origin in convalescence
5	12 F	2nd	Moderate pharyngeal. Tonsillar membrane O.A.; spread to anterior pillars of fauces	80,000 u. 2	4	Persistent albuminuria. Myocarditis; bradycardia, early bundle branch block	50	
6	7 M	3rd	Moderate pharyngeal. Membrane not extensive. Bilateral adenitis	70,000 u. 1	—	Palatal paresis. Myocarditis; extrasystoles	51	Partly inoculated against diphtheria
7	5 F	? 1st	Severe nasopharyngeal. Oedema of fauces. Extension of membrane 2nd day. Bullneck	100,000 u. 2	—	Persistent albuminuria. Acute myocardial failure (bundle branch block). Death	9	Early cardiac failure with vomiting and bradycardia. Died on 9th D.O.D.
8	24 F	3rd	Severe pharyngeal. Oedema of soft palate and fauces. Severe adenitis. Type, "gravis"	100,000 u. 1	5	Albuminuria. Myocarditis; persistent extrasystoles	47	Very ill 3 weeks A.A. Appeared on 11th "cardiac sickness" several times
9	6 F	2nd	Severe nasopharyngeal. Considerable oedema of fauces. Early bullneck	150,000 u. 3	17	Palatal paralysis	35	Note persistence of membrane on throat
10	35 F	6th	Severe nasopharyngeal. Extensive membrane but no faucial oedema	100,000 u. 1	9	Persistent albuminuria. Myocarditis; auricular fibrillation. Palatal paresis	71	
11	9 F	2nd	Moderate nasopharyngeal. Discrete adenitis	130,000 u. 2	7	Myocarditis; auricular fibrillation. Palatal paresis	79	Very toxic. Heart irregular for 7 weeks
12	31 F	5th	Moderate nasopharyngeal. Some faucial oedema. Early periaadenitis	110,000 u. 2	5	Mild palatal paresis	53	Persistence of pulse throughout
13	6 M	7th	Severe nasopharyngeal. Profuse rhinorrhoea. No oedema. Periaadenitis. Type, "mitis"	60,000 u. 1	5	Myocarditis; extrasystoles. Palatal paresis	75	
14	24 F	5th	Severe nasopharyngeal. Marked oedema of fauces, palate, and uvula. Post-nasal discharge	60,000 u. 2	3	Albuminuria. Myocarditis; cardiac sickness; extrasystoles. Peripheral neuritis	92	Absent early cardiac failure with vomiting. Very ill for 5 weeks A.A.

B.A. = Before admission. O.A. = On admission. A.A. = After admission. D.O.D. = Day of Disease.

present purposes at least. This paper is therefore confined to a comparison of the results obtained in cases treated with antitoxin and those treated with a combination of antitoxin and penicillin.

All the cases recorded here were under treatment during 1945 and January, 1946. The majority of the severe cases of diphtheria treated in hospital during that period had penicillin in addition to the usual dosage of antitoxic serum; they are referred to as the "penicillin series." A similar number of cases, comparable so far as is possible in respect to age, treated with serum only and comprising the remaining severe cases and a few that were rather less severe, admitted over the same period, were selected for comparative purposes. It must be emphasized that they were chosen for a high incidence of their initial lesion, and not because of a high incidence of complications. They are not, strictly speaking, a control series, in that they are not alternate severe cases as admitted. Indeed, a number of them are rather less serious than the penicillin cases. Thus one might expect better results, on the whole, from the control group than from the penicillin series.

None of the cases in either of the groups has been fully inoculated against diphtheria, because it is common experience that the immunized patient, however bad the initial lesion, almost invariably does well, escaping most complications. Therefore, one case of severe nasopharyngeal diphtheria treated with penicillin, and subsequently found to be fully inoculated, is not included in the comparison.

The age distribution of the penicillin cases is rather striking in that it shows a high proportion of adolescents and adults; this topsy-turvy state of affairs has been the experience in Gateshead recently. A further unusual feature is a marked disparity in the sex incidence of the cases, which is shown in the preponderance of females in the two groups.

Dosage and Administration of Penicillin

It is known that the causal organism, *C. diphtheriae*, is penicillin-sensitive (M.R.C. War Memo, 1944, No. 12), but as the disease is essentially toxæmic in nature the organisms, which are confined to the pseudo-membrane, are more or less cut off from the systemic circulation of the blood. It therefore seems doubtful, on theoretical grounds, whether the blood concentration of penicillin obtainable by the orthodox schemes of dosage would reach the organisms in the membrane in effective amount. Because of this doubt the early cases of the series were given double the usual dosage—that is, approximately 200,000 units in the 24 hours. Because of the shortage of penicillin for civilian use this heavy dose was continued for only 48 hours, but, later, doses of 100,000 units in the 24 hours were continued over 3 to 5 days. It is possible, of course, that with heavier and more prolonged penicillin therapy better results might be obtained.

The penicillin, preferably the sodium salt, was given in every case by three-hourly intramuscular injection. Local penicillin therapy was not used in any of the cases tabulated, though it is under trial.

Contents of the Tables

In order that the tables might be presented as clearly as possible they have been abridged; certain facts should therefore be borne in mind when analysing the contents: (i) The disease was confirmed bacteriologically by swabbing the lesion in all cases, though, unfortunately, typing was not carried out in every instance. (ii) In no case is the membrane confined to the tonsils alone. The cases dealt with are divided into "pharyngeal" and "nasopharyngeal," according to the anatomical distribution of the membrane and its associated symptoms and signs. A precise definition of these terms, which are in common usage, is, I think, unnecessary here. The pharyngeal and nasopharyngeal cases are subdivided into moderate and severe, in each case depending on the clinical severity. Throat diagrams have been omitted to facilitate printing. (iii) Antitoxin was given by intramuscular injection, unless stated otherwise.

Discussion of Results

There was one death in each series (Case 2, Table I, and Case 7, Table II). Both patients died from early myocardial failure, of the "cardiac sickness" type; their ages were 4½

and 5 years respectively. In the penicillin group there was only one case with multiple paralyses of any consequence (Case 9); while 9 out of the total of 13 escaped paralysis completely. In the control group only 4 out of 14 escaped paralysis. There were only 3 cases of clinical myocardial involvement in the penicillin series, as against 9 in the controls. The unexpected finding is that while penicillin seems to have little effect on the rate of clearance of the membrane, it does appear to reduce the incidence of complications. However, no conclusions can safely be drawn as a result of such a small series of cases.

The course of the disease is, as is well known, notoriously unpredictable; the severe case may escape all complication while a comparable subject with a milder attack may fall victim to one complication after another. This makes results very difficult to assess, and while we feel sure that penicillin caused a definite, even dramatic, improvement in some instances—Case 1, for example—it is impossible to be certain that any given patient would not have fared quite as well without it. In severe mixed infections, though, penicillin should be unquestionable value. I am left with the impression that penicillin therapy shortens the toxæmic state in nearly all cases, in addition to reducing the length of stay in hospital. A comparison of the tables shows, then, after due allowance has been made for the smallness of the numbers, that, in so respects at least, the patients receiving the penicillin far better than the controls. It should be remembered here, in addition, that because some of the controls were less severe attacks the control group might have been expected to do better on the whole than the others.

Summary and Conclusions

Thirteen cases of severe diphtheria were treated with systemic penicillin in addition to normal doses of antitoxin. The results obtained are compared with a similar number of comparable cases treated with antitoxin only. The results reported here show that while penicillin may not have the dramatic curative effect in diphtheria that it has in many other diseases, and can in no way supplant antitoxin, it appears to have been in some degree beneficial to most cases treated. In my opinion it should be given, together with antitoxin, to all cases of severe diphtheria.

I should like to thank Dr. James Grant, Medical Officer of Health for Gateshead, not only for permission to publish these cases, but also for his help and constant interest in this article.

A SHORT SURVEY OF TRILENE IN GENERAL PRACTICE

BY

A. BARRATT, M.B., M.Sc.

AND

S. H. B. PLATTS, M.B.

The object of this survey was to determine the usefulness of trilene in general practice. It was carried out in two independent practices for a period of six months. The points of reference were:—(1) Method of administration: (a) choice of appropriate apparatus; (b) technique. (2) Minor surgery especially as to the possibility of exploiting the known peculiar analgesic properties of trilene. (3) Midwifery.

Trilene (trichlorethylene; $\text{C}_2\text{Cl}_2\text{CHCl}$) was rediscovered as an anaesthetic in this country in 1941, after being used to some extent in America. It has a relatively high boiling point (87°C), which renders it unsuitable for administration on an open mask. In anaesthetic potency it occupies a place between N_2O and ether. During administration in Stage I there is a marked period of analgesia, use of which has been made in midwifery. For deep anaesthesia its use would appear to be limited to that of an adjuvant. It is alleged to have the property

of maintaining anaesthesia with a remarkably small dosage. It is, however, difficult and possibly dangerous to try to obtain the lower planes of anaesthesia by trilene alone. On no account should it be used in conjunction with a soda-ash canister, as the heat evolved has a deleterious action on trilene—dichloroacetylene being formed, which causes cranial nerve palsies.

Choice of Apparatus for Administration

It follows from the above that some closed apparatus was necessary for administration, and preferably one in which some rebreathing occurred, in order to warm the trilene with the heat of expired air. It was thought that the Clover inhaler (Hewitt) was a suitable instrument. Another instrument evoking interest from this point of view was the Oxford vinesthene inhaler. The latter was found a useful alternative for purposes of minor surgery, but, having only a small capacity (2 dr. 7.1 ml.), it was not so convenient for the purposes of midwifery, and as the Clover (Hewitt) was found to cover all requirements, used with or without the rebreathing bag, no further reference will be made to the vinesthene inhaler.

Technique

Minor Surgery.—Trilene was found to be a very useful anaesthetic in the hands of the single-handed practitioner: as will be seen from the illustrative cases, it allowed of careful and unhurried minor surgery in a variety of emergencies with the help of a pair of untrained hands. Many variations in technique, using Hewitt's modified Clover inhaler, were tried. And as a result of experience it appeared that there was a choice of two procedures:

1. Where the operation was of a very minor nature, and the amount of pain likely to be inflicted was very slight, it was necessary only to render the patient analgesic and not fully anaesthetized. Starting with the inhaler at 1/4 without the bag, and increasing to "full," the operator could then hand over to a bystander to hold the inhaler in place whilst proceeding with the operation. The patient was in this case usually not rendered unconscious, having felt no pain but sensation of touch only, although remembering what was said by others in the room.

2. When the patient expressly desired to be rendered unconscious, or when the operation was such as to be likely to inflict severe pain, the anaesthesia was continued to a deeper stage, and the patient so rendered completely unconscious for the duration of the operation. The inhaler was used as described above, and after a few breaths at 4/4 the bag was added. After a varying length of time automatic breathing indicated a satisfactory depth of anaesthesia. During the period in which the trilene was being tried out the operation was in many cases started before the onset of automatic breathing when it was thought that the patient would be sufficiently anaesthetized. Anaesthesia was usually found to be sufficient, but in order to be quite certain it was decided to wait until the onset of automatic breathing. Failing to do this accounted for one or two unsatisfactory cases of the series. After the stage of automatic breathing had been reached the bag could be removed and a bystander could hold the inhaler while the operation was completed, provided that this was not likely to be very long. Obviously, if a longer time was required it was necessary to have a second practitioner present. There was found to be a very considerable variation in the amount of trilene required for different individuals.

The whole procedure was very simple and enabled the single-handed practitioner to tackle many things that he could not otherwise manage by himself. Recovery was always very quick, and very complete, even when the anaesthetic was continued for a considerable period. Furthermore, the patients seemed to like it, and it was notable how very loudly it was praised by anyone who had had previous experience of other inhalational anaesthetics.

Midwifery.—Here the main use of trilene was as a self-help anaesthetic during the second half of the stage of dilatation. The inhaler was given to the patient (without the bag) set to 1/4 at first, and she inspired through the inhaler during the pain only. After a few pains the setting was increased to 1 2. pain only. At this setting she experienced considerable if not complete relief from pain, while still remaining co-operative. If the setting of 1/2 was not sufficient, it was increased to 3 4 for a time. The patient held the inhaler to the face during the pain only, laying it on the pillow at the side of her head in the intervals. It was found that after some considerable time, as more of the anaesthetic became absorbed, the setting could be reduced, and increased later for the actual delivery.

In a small proportion of cases there was a diminution in the strength of the pains; this was easily overcome by the injection of 0.5 ml. of pituitary extract. As with other sedative procedures, in one or two cases there was a slight post-partum haemorrhage. Provided that this possibility was foreseen, and a syringe containing pituitary extract was left handy, there did not appear to be any real danger of the haemorrhage being at all severe.

TABLE I.—Minor Surgery: Tabulated Results (All Cases)

No. of Cases	Treatment Given	Analgesia	Anaesthesia	Failures	Successes	Rapid Recovery	Absence of Sequelae
12	Incision: Boils	4			4	4	4
	Abscesses, etc., not involving digits	9	8		8	8	8
10	Stitching of lacerations			1	9	9	9
1	Including midwifery		1		1		
1	Manipulation of toe	1		1		1	1
	Operations:						
6	Involving digits	3		3		3	3
	Whitlow, avulsion of nails, etc.		3		3	3	3
4	Dilatation of multiple urethral structures (one individual)				4	4	4
33		21	12	5	28	33	33
17	Above cases treated with analgesia, less those involving digits	17		1	16		

The sole criterion of success or failure was whether the patient felt any pain.

TABLE II.—Midwifery: Results with Trilene Alone

	Failures	Partial Failures	Successes	Successes with Amnesia	Total
Primiparae	0	2	9	2	13
Multiparae	0	1	6	2	9
Total	0	3	15	4	22

"Failure" = Little or no relief from pain.

"Partial Failure" = Patient difficult to control and unco-operative.

"Success" = Patient had great relief from pain and remained co-operative and controllable throughout.

TABLE III.—Midwifery: Trilene followed by Ether*

	Cases	Slowing of Labour	Slight P.P.H.	Slowness of Recovery	Unpleasant Sequelae	Maternal and Foetal Deaths
Primiparae	5	1	1	1	0	0
Multiparae	0	3	1	0	1	0
Total	5	4	2	1	1	0

*Forceps or other operative procedures performed under open ether anaesthesia subsequent to the use of trilene self-help analgesia.

A Few Selected Cases

1. **Minor Surgery.**—(a) Successful analgesia (2 cases); (b) a case of unsuccessful analgesia; (c) successful anaesthesia in a similar type of case to (b).

II. **Midwifery.**—(a) An ordinary successful case; (b) an ordinary successful case plus amnesia.

Group I (a). Mrs. B., aged 56, fell on some stone steps, sustaining a large laceration on the front of the leg below the patella, 2½ in. (6.3 cm.) long, involving subcutaneous tissues; the patella tendon was showing. Trilene was administered for toilet of the wound and the insertion of two silk-worm-gut sutures. The Clover inhaler was used, starting at 1/4 and increasing to 3/4 without a bag. After 10 to 12 breaths the toilet was started and sutures inserted. Recovery was very rapid, and the patient felt no pain whatsoever. She did not completely lose consciousness, but felt that something was being done to the knee, and could see the practitioner as a vague black shadow. She was quiet throughout.

Mrs. F., aged 50. Obese subject; abscess of abdominal wall, probably a suppurating sebaceous cyst. She expressed a wish not to be rendered unconscious. Trilene was given in Clover's inhaler without a bag, gradually increasing to 4/4, and the abscess was opened. She had not lost consciousness, and had felt no pain, although she could tell that something was being done to her abdomen.

Group 1 (b).—Mr. P., aged 35. Subungual whitlow of index finger. Trilene was administered without a bag, increasing from 1/4 to 4/4. He was a big ex-Army man of 13 st. (82.5 kg.), and his was an unsatisfactory case. He nearly jumped off the bed when the nail was removed, and said afterwards that he felt it being avulsed.

Group 1 (c).—Mrs. W., aged 30. Large subungual whitlow of finger; she felt ill and was suffering greatly. The terminal phalanx was two to three times its normal size. She was anaesthetized to the stage of automatic breathing. The nail was removed and pus released by probing with forceps. Recovery (1½ minutes) good, but pain from the finger then made the patient a little faint. She had of course felt no pain during the operation.

Group II (a).—Mrs. H., primipara aged 22. Vertex presentation L.O.A. Administration started at 10 p.m.; one-third dilated. Delivery at 3.30 a.m. The patient continued to self-administer up to and including delivery; setting, 3/4 followed by 1/2 for the greater part of the labour; last 10 minutes, 3/4. She did not remember the birth, and had very little pain. The period 10 p.m. to 3.30 a.m. seemed more like two hours. She was enthusiastic, and stated that after three breaths at 3/4 she lost all pain.

Group II (b).—Mrs. G., primipara aged 24. Occipito-anterior presentation. Started in labour at 8 months. In pain all night; first seen at 9 a.m. Taken to nursing home and found to be one-third dilated. Trilene, self-administered, 1/2 to 3/4; delivered 11.30 a.m. The child weighed 4 lb. 14 oz. (2.2 kg.). Immediately after delivery she sat up and took tea, talking rationally. The patient said she had had hardly any pain. Next day she denied any knowledge of labour subsequent to receiving the anaesthetic, or of sitting up, talking, and taking tea immediately after delivery. She spoke of her surprise, the previous afternoon, to find that she had had her baby.

Conclusions

Minor Surgery.—Provided that very painful procedures—e.g., operations on digits—are avoided, the use of the analgesic properties of trilene in minor surgery seems quite feasible. With the exception of operations on digits, the only analgesic failure was in the case of a child who became very excited and uncontrollable. However, as our experience and confidence increased we learnt more to the view that mild anaesthesia in all cases is the more satisfactory procedure. Recovery is rapid and without sequelae, and the agent has not given rise to the least anxiety. Used as a light anaesthetic for minor surgical procedures it appears quite safe.

Midwifery.—An interesting and otherwise unencountered property of trilene has come to light. In rather more than 20% of cases complete amnesia followed its use. With careful instruction, and close observation of the patient in setting the apparatus, it is thought that this figure might be raised a considerable extent. It is a very useful and gratifying phenomenon.

One partial failure was in a case in which the practitioner was summoned at the very end of labour, and trilene used for only about 10 to 15 minutes. The patient was excited and overwrought, and, quite frankly, chloroform would have suited the case better. Used in place of chloroform in the last few minutes of labour, trilene does not show its full range of capability; here the field should be left to the older drug.

The other two partial failures were both relegated to that category owing to the action of premedication (chloral and seconal), and we roundly condemn its use in conjunction with self-help trilene analgesia. The patients were rendered restless and unmanageable, and could not self-administer the trilene.

Comment

The cheapness of the method is phenomenal; 1 oz. (28 ml.) of trilene will last, as used in midwifery, 3 to 5 hours, at a cost of less than 6d.

The wide variation in the requirements of trilene in different individuals, and in the same individual at different stages in midwifery, necessitates a variable administrator for the full exploitation of its remarkable properties. Attention is drawn to this particular point because the fixed type of administrator is tending to become popular in midwifery. We see no reason why midwives should not use the Clover (Hewitt) without the bag.

The general practitioner has in trilene, used in Clover's inhaler, an excellent alternative to the heavy, cumbersome, and expensive N₂O apparatus, both for midwifery and for minor surgery.

UNDULANT FEVER COMPLICATED BY ACUTE TRANSIENT ATTACKS OF APHASIA AND DURING CONVALESCENCE, BY DEAFNESS, TINNITUS, AND PARAESTHESIA

BY

G. JOLY DIXON, M.A., M.D., M.R.C.P.

AND

ROBERT ROAF, M.A., F.R.C.S.

The occurrence of symptoms suggesting mild involvement of the nervous system during the course of undulant fever is recognized. In 1934 Krabbe estimated meningitis and neural pains as occurring in 75% of cases. Actual recovery of causative organism from the central nervous system was first described by Hughes in 1897; and De Jong in 1936 collected nine similar observations from the literature and added one of his own. However, definite neurological signs are not commonly recognized. Dalrymple-Champneys (1943) reports meningitis in only three of his collected series of 616 cases; and Har Jordan, and Borts (1936) in reviewing 1,080 cases mentioned "meningitis and meningo-encephalitis—one case simulating brain tumour," indicating that these complications are rare.

A different experience is recorded by Leys (1943), who, reporting eight consecutive cases of undulant fever, found meningism in two and transient aphasia in a third; while Pos and Smith (1936) consider that Brucella infection should be suspected in any case of atypical meningitis. Roger (19) reviewed the literature and described the neurological complications of undulant fever as cases of: (1) paraplegia, majority with only motor involvement, but in others there occurred sensory and sphincteric disturbances and pachymeningitis serosa circumscripta; (2) cerebral complications such as hemiplegia and insanity; (3) both isolated and periphereal neuritis; (4) chronic leptomeningitis.

Case History

On August 8, 1944, a medical practitioner aged 31 developed headache, malaise, fever, shivering, and some photophobia. The next day he was better and his temperature returned to normal. He had spent August and September of the preceding year in Sicily. Blood films were taken two-hourly and examined; in 11 of 19 film trophozoites of *Plasmodium vivax* were found. He was given an appropriate seven-day course of quinine and mepacrin on the last day of this treatment shivering and pains in the region of both sacro-iliac joints occurred. Subsequently his illness followed the usual pattern of undulant fever, with intermittent pyrexia and a curiously rapid alternation of well-being and malaise. Unusual features were attacks of meningism, during which Kernig's sign became positive.

On Oct. 9, at about 5.30 a.m., he suddenly became extremely excited, and thoroughly alarmed his wife and the doctor she called in. This condition subsided at about 7 a.m. When I saw him at 9 a.m. his temperature was 99° F. (37.2° C.) and he was fully conscious but photophobic and uncommunicative, and complained of headache. Kernig's sign appeared on lifting either leg to 65°.

The illness resumed its usual course until, on Oct. 19, at 6.20 p.m. he started to shout; but when the nurse came to him he appeared rational, though she could not at first understand him. I saw him 35 minutes later, when he was obviously rational and quite comprehensible, though slightly dysphasic. At 7.20 p.m. I was called back as he had become very excited. He seemed to understand what was said, and on the whole acted rationally but spoke gibberish. He was obviously intensely anxious to impart some information, but was unable to find the words. Certain phrases kept recurring in their correct context; for instance, he repeatedly said, and obviously meant, "Pay great attention." His mood, however, was far from

rmal; he readily became irritated at not being understood, and owed an impatience quite foreign to his usual temperament. There were no other abnormal neurological physical signs at this time. However, his comprehension of speech was so good that it proved possible, with the help of his wife, to devise a system of questions, which he had only to affirm or deny. He was thus able to impart at his mother suffered from migraine, and that he had a fortification spectrum or some similar visual disturbance and desired me to give him an injection of "femerger." Directly he had imparted this information he settled down quietly. Objectively he regained his usual speech on waking next morning. At this time the optic disks showed an appearance suggestive of early swelling which had not previously been present and which had certainly subsided when he was examined in March, 1945. On Oct. 30 he had a further attack of aphasia, which was diagnosed by an experienced ward sister as lithium. From the subjective point of view the attacks came on about five minutes without previous warning or obvious cause, it associated with a feeling of strangeness and visual hallucinations, which were recognized as such. The patient never lost consciousness, and could always understand what was said to him, and even read and grasp the meaning of what he read. He retained full sight and the powers of reasoning. For instance, at the time he thought the first attack was due to a cerebral embolism, and on another occasion, when he wanted an injection of "femerger," he repeated the advertisement columns of the *British Medical Journal* to demonstrate his idea. He could not write word but only individual letters. He noticed slight dysphasia for a few days after each attack.

The attacks of aphasia were associated with a severe paroxysmal headache. From the third to the ninth month of the illness attacks of classical migraine occurred frequently, at first almost daily; the patient had not previously suffered from migraine, and it has been since recovery.

Although obviously far from completely recovered, he returned to work on March 1, 1945, and soon became aware of a persistent tinnitus, progressive deafness, and tingling of the legs and arms. These symptoms became progressively worse during the summer of 1945, and by the end of June he had developed a moderate degree of auditory-nerve deafness. An otologist who was consulted expressed the opinion that the tinnitus, deafness, and absence of findings in the middle ear were suggestive of a hereditary degenerative condition. However, it would appear that these symptoms were a manifestation of undulant fever, as he found that he had a slight vertigo during this period. The next winter the headache, tinnitus, and paraesthesiae gradually disappeared, and his hearing improved the same time.

The diagnosis was established by the rising blood titre of agglutinins against *Brucella abortus*; thus serum collected on Sept. 2, 1944, caused agglutination of this organism up to dilutions of 1 in 160, while serum collected on Sept. 9 caused, after 48 hours, agglutination in dilutions of 1 in 1,280 and after 48 hours in dilutions of 1 in 5,120. It is considered unlikely that malaria had any part in the symptomatology after August, 1944, as frequent subsequent examinations of the blood for malaria parasites were persistently negative.

Summary

A case is described in which the patient had undulant fever with intermittent pyrexia for about 21 months; during this period he suffered three attacks of pure motor aphasia and, when almost convalescent, progressive nerve deafness and tinnitus. He ultimately made a complete recovery.

ALTERATIONS IN THE "B.P."

The General Medical Council announces certain alterations in the *British Pharmacopoeia*, 1932. The amendment to the monograph on strychnine, ferr. phosph. & quinin. et strychn. (Easton's syrup), which was authorized in the Sixth Addendum, pages 26 to 28, is annulled. The dried root or rhizome of *Cephaelis acuminata* Karsten, known in commerce as Cartagena, Nicaragua, or Panama ipecacuanha, may now be used as an alternative to the dried root of *Cephaelis ipecacuanha* (Brot.) A. Rich. The requirement that the 2% of the total alkaloids of ipecacuanha, calculated as emetine, in root or powdered ipecacuanha must consist of a definite proportion of non-phenolic alkaloids is deleted.

Medical Memoranda

Carcinoma of the Bladder Associated with Presence of a Stone

I would like to place on record the following interesting case, which would appear to support the factor of chronic irritation in the aetiology of carcinoma of the bladder.

CASE RECORD

A man aged 55 was admitted to hospital on May 23, 1944, because of severe haematuria of two weeks' duration. His history revealed that in 1935 he had had an attack of frequency of micturition and dysuria which had lasted but a week and then cleared up. From that time until his admission he had been subject to frequency of micturition. Examination showed that he was passing what appeared to be practically pure blood. He was shocked and exsanguinated. Rectal examination revealed a prostate of normal size for his age, but the base of the bladder was rather tender. Radiographs taken soon after admission revealed a stone in the bladder. The centre of the stone appeared to be composed of some completely radio-opaque substance, whereas the more peripheral parts were less dense. Blood transfusions were given and cystoscopy was performed under spinal analgesia, and although nothing could be seen because of the large amount of blood in the bladder, the stone was distinctly felt with the tip of the cystoscope. Adrenaline bladder-washout rendered the bleeding less copious, and four days later suprapubic cystostomy was performed, again under spinal analgesia, and the stone was removed. The stone was chocolate-coloured and of irregular outline but highly polished. It measured 1½ by 1 by 1 in. (3.8 x 2.5 x 2.5 cm.). It was cut open along its long axis to determine the cause of the opacity mentioned above, and was found to contain a rifle bullet of a calibre similar to those used in Service rifles (see

Photograph of inside of stone after section, showing the bullet.

illustration). Further questioning of the patient revealed that in 1913 he had been wounded in the upper part of the right thigh, and had sustained a fractured femur on that side, but no history of any symptoms which would support a vesical injury could be elicited. Unfortunately the patient collapsed and died suddenly eight days after the operation.

Post-mortem examination revealed that death was due to bronchopneumonia, and also that the bladder base was infiltrated with a ring of carcinoma. Histological examination of a section of the growth revealed it to be of epidermoid type.

The points raised by this case would appear to be: (1) Did the bullet lodge in the bladder at the time of wounding in 1913, and so form a nucleus for stone formation? If this were so, it is indeed surprising that no symptoms had been noticed at the time of injury. (2) Was the carcinoma due to the long-continued presence of the stone? Secondly, the epidermoid character would presume a metaplastic change preceding the onset of malignancy.

I am indebted to Mr. A. Holley, M.B., F.R.C.S., for permission to report this case.

Queen Elizabeth Hospital, Birmingham

Labial Adhesions in Children

Adherence of the labia minora in children is a condition that is often seen in the out-patient department of this hospital. It does not seem to have gained the recognition either of the general medical practitioner or of the commensurate textbook. In paediatric textbooks it is usually found under the title "atresia of the vulva." It is not an atresia, but a simple adhesion; and, though the aetiology is obscure, it is not

that a previous mild attack of vulvovaginitis, which is very common among children of poor hygiene, is a factor.

It is as a rule first noticed by the mother when washing the child, or, at a later date, at a routine examination. It may be diagnosed as a rare congenital abnormality, such as complete atresia of, or a membrane occluding, the vagina. There is never any obstruction of the passage of urine, but some vulvitis and consequent dysuria may be present as the result of imperfect hygiene.

The treatment is simple when once the nature of the condition has been appreciated. The labia minora can often be separated simply by steady, gentle pressure, stretching them apart. An anaesthetic is sometimes necessary to free them, and separation can then be readily effected with a probe. There is almost always some oozing from the freed edges, but this is never severe and it needs no haemostasis. It is important that the vulva be lubricated for a day or two after freeing to prevent the formation of new adhesions; but even when this is done they occur occasionally.

The prognosis is complete recovery and normality, and the mothers should be reassured on this point.

I am indebted to Mr. T. Twistington Higgins for permission to publish this note.

Noma Treated with Penicillin

The condition of gangrenous stomatitis, or noma, though a well-recognized clinical entity, is now seldom seen in England, but in Aethiopia it appears to occur more frequently, and until the arrival of penicillin it carried a high mortality (approximately 80%). Below are given brief reports of three cases treated with penicillin, all of which showed a highly satisfactory response.

CASE RECORDS

Case 1.—An Aethiopian woman aged about 30 was admitted complaining of a sore mouth and soreness round the vulva. She was ill, pale, and febrile, with large white ulcerating patches on her tongue, gums, and inner aspect of the lips, and similar ulcerations on the labia majora and minora. The Wassermann and Weil-Felix reactions were negative, as were the direct blood smears; smears from the ulcers showed spirochaetes and fusiform bacilli of the Vincent type, together with streptococci and staphylococci. In addition to local cleansing and general care, the patient received an injection of neoarsphenamine (0.6 g.) on the day of admission and again two days later. In spite of this the process was spreading, and patches of black gangrene were appearing on the outer aspect of the lip and also on the vulva. On the fourth day sulphapyridine was started—7 g. that day and 5 g. on each of the two succeeding days—but the gangrene was still spreading and the general condition was worse. Penicillin was started on the seventh day—25,000 units every three hours for five days. A transfusion of a pint (568 ml.) of citrated blood was also given on the seventh day and local treatment with hydrogen peroxide was continued, but the sulphapyridine was stopped. Within 24 hours of starting this treatment the gangrenous patches had become sharply demarcated, and by the fifth day they had separated, leaving clean ulcers. Penicillin was then stopped, and the condition did not relapse.

Case 2.—An Aethiopian boy aged 4 was admitted, having been ill 12 days with headache, fever, and a rash, probably measles, of which there was an epidemic in the town at the time. For two days a black patch had been noticed on the right cheek and slight fever persisted. He was pale and febrile (T. 100° F. (37.8° C.), P. 100). On the skin externally, with discharging pus, erythema and oedema. Inside the mouth there was a moist grey patch involving both the inner side of the cheek and the upper jaw. Direct smears from this revealed spirochaetes, fusiform bacilli, streptococci, and staphylococci. Penicillin was started at once, and in all 300,000 units were given in three days. The process immediately became sharply demarcated and a slough rapidly separated, leaving a clean through-and-through hole 1 in. (2.5 cm.) in diameter in the cheek. A small bony sequestrum did not separate for some days, but progress was satisfactory. At the time the patient was also suffering from acute amoebic dysentery, which responded to treatment with emetine.

Case 3.—An Aethiopian boy aged about 8 was admitted, also following an attack of presumed measles, with a grey gangrenous patch on the inner aspect of the cheek. Except that the skin was not yet involved, the appearance was identical with that of Case 2. His general condition was satisfactory (T. 100° F., P. 100). Penicillin was started at once, 300,000 units being given in the course of four days. The result was again an immediate demarcation and rapid separation of sloughs, but this time without loss of external skin at all.

COMMENT

The first case occurred at a time when penicillin was very scarce and could be given only if life was endangered; sulphenamides had been tried and proved inadequate. There can be little doubt that had penicillin been given at once, as in the other two cases, much suffering, danger, and deformity would have been avoided.

Medical Hospital, Addis Ababa, Aethiopia

Reviews

AETIOLOGY OF SCROTAL CANCER

Cancer of the Scrotum in Relation to Occupation. By S. A. Henry, M.D., F.R.C.P., D.P.H. (Pp. 112; illustrated, 15s.) Oxford Medical Publications. London: Oxford University Press, 1946.

Cancer of the scrotum is relatively rare, occurring in about five per million of the male population, but it is of great interest and importance as the first and outstanding example of human cancer in which the predominant causative factor can be identified. Dr. Henry's short book is valuable as a contribution to cancer research as well as to industrial medicine. The clinical features, course, and treatment of the disease are described briefly. A summary of the history of cancer of the scrotum as an industrial hazard since Percival Pott in 1773 noticed its frequency in chimney sweeps leads to the author's main contribution, which is an analysis of the probable causative factors.

The value of Dr. Henry's discussion of the statistical data is enhanced by his close acquaintance with industrial life and by his personal inquiries into individual case histories. Since 1920 epitheliomatous ulceration of the skin has been a notifiable disease under the Factories Act; 3,333 cases had been notified up to the end of 1943 and about 40% of them were cases of cancer of the scrotum, more than half of these being in cotton-mule spinners. Taking into account the number of workers at risk the incidence was highest in chimney sweeps, followed by patent-fuel makers, cotton-mule spinners, and men employed in the distillation of tar and the manufacture of coal-gas and coke. In the majority of cases, exposure to tarry products or to mineral oils was accepted as the causal factor, but in about 20% of the cases no probable causal factor was identified. The scrotum is the commonest though not the only site of epithelioma even in chimney sweeps and cotton-mule spinners. In terms of laboratory experience, the carcinogenic potency of the noxious materials must be accounted low, for cancer develops in only a small proportion of the exposed worker and the induction period is long. Cancer of the scrotum was not found in cotton-mule spinners who had started work less than 16 years previously; commonly it occurred 40 to 50 years after starting work. Many men had ceased to be employed as cotton-mule spinners for many years before developing cancer and some had been retired from all work for long periods as, for example, for 35 years, when cancer first appeared. As in laboratory experience, cancer can develop long after the inducing stimulus has ceased to operate. It is less clear how long the stimulus must operate in order that cancer shall occur after long delay without further exposures to the carcinogenic agent. Dr. Henry cannot settle this important question, but he finds indications that exposure for one or two years may be sufficient. Further inquiry is evidently required.

The book is well illustrated by photographs of lesions and of industrial processes, and it is enlivened by reproductions of old prints and by many interesting sidelights on industrial and social history.

PHYSIOLOGY AND MEDICINE

The Physiological Basis of Medical Practice. By Charles Herbert Best, M.D., D.Sc., F.R.S., and Norman Burke Taylor, M.D., F.R.C.S. Ed. Fourth edition. A University of Toronto Text in Applied Physiology. (Pp. 1,169; 497 illustrations. 55s.) London: Baillière, Tindall and Cox, 1945.

This textbook is about a third longer than the Bible, and if used as a script for broadcasting it would occupy the B.B.C. Home Service programme continuously for nearly a fortnight. One is astonished at the mere physical achievement of the authors in writing or dictating so many words, and one is further astonished at their energy in producing four editions over a period of nine years, particularly as six of them were years of war in which the authors took an active part. The book is divided into nine sections, dealing respectively with the blood and lymph, the circulation of the blood, respiration, the excretion of urine, digestion, metabolism and nutrition, the ductless glands, the nervous system, and the special senses.

Each section consists of approximately 100 large pages with two columns to a page, so the treatment is frankly encyclopaedic. The book is well illustrated, though the photographic reproductions are poor; there is a coloured plate illustrating the blood cells.

So far as we have been able to test it, the book is admirably up to date. The subtitle, "A Text in Applied Physiology," accurately defines its scope and limitations. Its scope is the whole of physiology, and its limitation that not a great deal of physiology can be profitably applied to medical practice. Our criticism therefore is that it is much too large and detailed to be used as a textbook, and that it is very doubtful whether one book can effectively deal with physiology and its applications. It might be better for physiologists to teach physiology, and the clinical scientists to teach its applications. We should then have less about the physiological basis of muscular contraction, which is in any event contentious; more about the physiology of joints, fasciae, and ligaments; less about the chemical properties of haemoglobin; and more about the air-conditioning apparatus in the respiratory tract, and so on. The problems which puzzle us in medical practice are not the applications of chronaxie or the cardiac output, but the meaning of pain and sleeplessness, of flatulence and heartburn and the like; and these are just the problems on which our physiological colleagues give us least help. They are rightly and properly interested in the growing points of their subject, but they are not so justified in assuming that these things are of general interest. The idea that the whole of physiology can usefully be applied to medical practice is surely as outmoded as the idea that the student should learn every detail of man's anatomy. Genetics, statistics, biochemistry, and psychology all now claim a share in the teaching of normal human function, and we should therefore prefer to see textbooks of medicine for the student showing more of the influence of the basic sciences, rather than see textbooks of the basic sciences growing ever longer.

"Best and Taylor" is a magnificent achievement of intellectual synthesis, and it should be of great value to the advanced student and research worker, but it is not the solution to the problem of bridging the gap between the preclinical and the clinical sciences. We still await the writer who will reorientate the teaching of applied physiology and preliminary medicine in the same way as MacCallum set pathology on a new road after the war of 1914-18.

TROPICAL NUTRITION

Tropical Nutrition and Dietetics. By Lucius Nicholls, M.D. Second edition, rewritten and enlarged. (Pp. 370; 32 illustrations; 11 plates. 27s. 6d.) London: Baillière, Tindall and Cox. 1945.

Knowledge of food constituents is increasing rapidly and Dr. Lucius Nicholls may be complimented on his effort to keep his book *Tropical Nutrition and Dietetics* in line with present knowledge. The second edition includes the later findings on vitamin K, nicotinic acid, pyridoxine, biotin, choline, etc., and even something about the "minor vitamins." This term is used somewhat apologetically for those which are very unlikely to be deficient from human diets, but the reviewer considers that they may prove to be just as important as those "major vitamins" whose functions are better known. It seems a pity that this term should have crept into the literature. Two chapters on foodstuffs peculiar to tropical climates (their production and preparation), one on food poisoning and one on insect pests of grain foods, and further information on public health activities in relation to nutrition have been added. There are also descriptions of diets suitable for use in hospitals, prisons, and other institutions.

The book gives much useful and interesting information that might be difficult and would certainly be laborious to find elsewhere. As appendices it contains many useful analytical methods and tables—e.g., the examination of the blood in anaemias, certain tests for vitamins, a dentition table, a determination of prothrombin in blood, instructions for dietary inquiries, average heights and weights of fairly well-grown boys and girls, the A.C.H. (arm, chest, hip) index of nutrition, nutritional section of a food craft exhibition in Ceylon, etc. There are thirty-two figures, some of them photographs and others clear pen drawings. The form of the book, binding, printing, and paper are very good for a "war-time" production.

MEDICAL ENTOMOLOGY

Entomology (Medical and Veterinary). By D. N. Roy, M.D., D.T.M. (Pp. 358; illustrated. Rs. 30.) Calcutta: Saraswati Library, College Street Market. 1946.

"Entomology," says Dr. Roy, "is no longer restricted to insects alone but it includes the study of the whole phylum Arthropoda." With this fiat, he allows himself scope to deal with most of the smaller vermin encountered by medical men, especially in the Tropics. The range of subjects treated should make the book a useful one and the profuse illustrations are of considerable assistance in identification.

Unfortunately a closer examination of the book reveals quite a large number of small errors and ambiguities. We may quote some statements taken at random to illustrate this: p. 11 (of the cockroach), "Ants and other hymenoptera often parasitise the egg pod"; p. 273, "Lice are usually killed by thirty minutes immersion in water . . ." (not true), and "Wind may be responsible [for spreading lice] to a small extent by blowing the nits" (nits are firmly attached to hair or garments); p. 268, "The main features of this order (Anoplura) are . . . (2) the integument is highly chitinated" (does he mean "not highly chitinated"?); p. 326, "The egg (of *Sarcoptes*) is ovo-viviparous . . ." (?); p. 289 (speaking of control of bed bugs), "French chalk is a good insecticide" (not true). In dealing with the Arachnidae, Dr. Roy has obviously confused the superfamily Ixodidae with the order Acarina. If one transposes the two words on page 291 (where they occur as major headings!) his text reads correctly.

The control sections are perhaps the weakest parts of the book, for the most recent methods and materials are either omitted or are given with small errors in the directions for use, which sometimes vitiate the whole procedure. In general the whole work gives the impression of being rather hastily finished. Considering that the scope and treatment lay the foundations of a very useful handbook, it is a pity that more care was not taken with these essential details.

Notes on Books

The very popular textbook *A Short Practice of Surgery* by Hamilton Bailey and R. J. McNeill Love was first published in 1932, and after six revisions and five reprintings appears now in a seventh edition (H. K. Lewis and Co.; 40s.). Owing to the inclusion of new material the present volume is somewhat larger than its predecessor; with the index it runs to nearly 2,000 pages. Many chapters have been rewritten and there is an additional one on the larynx. New illustrations have been added and some of the former figures are replaced, bringing the total number to 1,063, of which 203 are coloured. The printing and general lay-out of the book are most satisfactory. As before, advanced surgery and rare conditions are relegated to small type, which is quite legible. This edition also includes a glossary of anatomical names, giving in parallel columns the page reference, the structure mentioned in the text and the equivalent term in the Birmingham revision of the B.N.A.

The Autonomic Nervous System by Dr. ALBERT KUNTZ (London: Baillière, Tindall and Cox, 42s.), which has already an established place in the literature of the autonomic nervous system, has in its third edition been thoroughly revised and in part rewritten. The chapters dealing with the central control of autonomic functions, including cortical influences as well as hypothalamic, and the newer information regarding conduction paths, are representative of the present-day views; clinical bearings are abundantly introduced. The general get-up is excellent.

The first number of *Tuberculosis Index and Digest of Current Literature*, dated March, 1946, has been published for the Tuberculosis Educational Institute by the National Association for the Prevention of Tuberculosis, with a foreword by Sir Francis Fraser. The aim of this periodical is to give a complete list of current articles on all aspects of the disease as they appear in world scientific and medical literature. The list is made up of articles published in the preceding three months. The *Tuberculosis Index and Digest* is divided into 23 main sections, each under the supervision of an expert. The annual subscription is 15s. or 54s., and communications should be addressed to the Editor, N.A.P.T., Tavistock House North, Tavistock Square, London, W.C.1.

Nova et Vetera

THE LONDON LOCK HOSPITAL AND ITS FOUNDER

The bicentenary of the London Lock Hospital, founded July 4, 1746, lends interest to the details of the life of the founder, William Bromfeild (as he always spelt his name), whose initiative made its existence possible.

William Bromfeild (1713-92) was the son of Thomas Bromfeild, M.D.Oxon, and Mary Briggs, daughter of William Briggs, M.D., physician to William III and to St. Thomas's Hospital. He was born in New North Street, Holborn, and was baptized July 30, 1713. He early attracted the interest of John Ranby (1703-73), Serjeant-surgeon to George II and first Master of the Corporation of Surgeons after their separation from the barbers (1745). It probably was Ranby's influence which got him appointed demonstrator of anatomy at Barber-Surgeons Hall in 1744, and surgeon to St. George's Hospital on August 9 of the same year. Next year he became surgeon to the Prince of Wales, who was President of St. George's, and on his death in 1751 continued as surgeon to the Dowager Princess.

It was at this period in 1746, at the age of 33, that Bromfeild founded the Lock Hospital on a site half-way down Grosvenor Place from St. George's. There he bought the remaining 95 years of a 99-year lease of "the house lately in the possession of Mr. John Cooper" for £350, and a ground rent of £10 annually, paid to Sir Robert Grosvenor, Bt. This he sublet to the Trustees of the Hospital for £17 10s. a year plus the ground rent until such time as they could repay him the £350 purchase money, and so have legal possession. The hospital was opened with 30 beds on Jan. 31, 1747, and it has continued its charitable work ever since.

Bromfeild must have been a good mixer, for his practice became large and fashionable, and he was able to gather an influential list of patrons and subscribers to his hospital. Obviously it was very badly wanted in the West End, for of the 442 patients admitted in 1758 "one hundred were married women, some with infants at the breast, many of whom were admitted almost naked, penniless, and starving."

At that time there were still two Lock Hospitals in London, one in Southwark for men and one in Kingsland for women. These two were all that were left of the seven lazaret houses controlled by St. Bartholomew's Hospital after the Dissolution of the Monasteries. But both of them were closed in 1760, and Bromfeild's hospital was thus left to carry on alone in London for roughly the next 160 years. In 1760 he became one of the Court of Assistants of the Surgeons Company. In 1768 he was Senior Warden, and in this capacity passed John Hunter for his diploma. In 1769 he was Master, and in the same year made surgeon to Queen Charlotte, wife of George III. In 1780 he resigned at the age of 67 from the Court of Assistants, and also from St. George's after 36 years' service.

He had two sons and a daughter. The elder son, William Heriot Bromfeild, M.D.Padua, died in 1762. The younger son, Charles Bromfeild, succeeded his father as surgeon to the Lock Hospital in 1770 and as assistant surgeon to St. George's in 1778; but he predeceased him in 1784. An engraving of Charles is often mistakenly catalogued for that of his father, of whom only three authentic portraits are known: one by Vandergucht, one by Cosway, and one painted by Nathaniel Dance in 1773 which is now in the Lock Hospital.

According to Ottley (*Life of John Hunter*, p. 25) Percival Pott ranked highest as a surgeon in this period, "but the second stations were ably filled by Bromfeild, Sir Caesar Hawkins of St. George's, and Samuel Sharp and Warner of Guy's." He published a small work in Latin, *Observationes ad lithotomiam attentiores aliaque Chirurgiae Monumenta*, Florence, 1761; but his *Chirurgical Observations and Cases* published in 1773 is Bromfeild's main contribution to surgical literature.

He seems to have had certain literary tastes and to have been on friendly terms with the artistic and musical world. He adapted an old play *The City Match*, and under the title of *The Schemers* this was produced by Garrick at Drury Lane for the benefit of the Lock Hospital. Benefit plays were given annually for the hospital at Drury Lane and Covent Garden. Garrick, J. Rich, Board, and Giardini were his friends; and he persuaded Foote, Powell, and Macklin to play for him. Handel gave the first performance of *Judas Maccabaeus* to the hospital after Bromfeild had operated on him for cataract.

Any account of his life would be incomplete without reference to the Rev. Mr. Madan, the brilliant eccentric preacher who founded the Lock Chapel and made such a success of it that he was able to contribute from the pew rents £1,000 a year to the hospital funds. Madan's sermons drew large congregations. He was a musician and published a book of hymns. He was a friend of John Wesley and secured Charles Wesley as organist to the Annual Oratorio in

the Chapel. He was a cousin of Cowper the poet. Between him and Bromfeild they kept the hospital going financially up to 1780, by which time it was soundly on its feet. Both resigned from the hospital that year owing to differences with the Board. Both were forceful dictatorial men and resented innovations which were necessary. Madan died in 1790. Bromfeild followed him, full of years and honours, in 1792.

J. J. A.

EARLY METHODS OF ANAESTHESIA

Ancient Anodynes. Primitive Anaesthesia and Allied Conditions. By E. S. Ellis, M.R.C.S. With foreword by T. K. Penniman, M.A. (21s.) London: William Heinemann Medical Books, Ltd. 1946.

In this attractively printed and bound book Dr. Ellis has gathered from some hundreds of sources anecdotes and fact about the attempts of all races to subdue pain and obliterate sensation. He has researched into methods of "physical anaesthesia," the production of unconsciousness by a blow before performance of an operation; into "psychological anaesthesia" or forms of "mesmerism"; and into the inhalation of drugs to produce anaesthesia. References to various sleep-giving drugs were made in literature four centuries before Christ, and biblical references have not been neglected in the exhaustive catalogue. Like the results of an excavation, sorted, classified, and displayed, the book offers a series of facts almost entirely without comment. "Mr. Penniman in his foreword says 'it is a work of reference rather than one to be read straight through.'" Certainly for one who wishes to know of literary references to early methods of anaesthesia it will be invaluable. Attention is drawn in the preface to the fact that the war has made it impossible to finish the book in the form originally intended. The material which the author has compiled is such that one wishes it had been presented, as it could have been, in a completely absorbing form. This is left to those who will use Dr. Ellis as their source of reference. The book concludes with two chapters on the history of modern anaesthesia; these are less staccato and breathless than the rest of the book, but remain the brief collected stories of the participants in the discoveries of ether, nitrous oxide, and chloroform as anaesthetic. There is a full list of the authorities quoted.

THOMAS BILL, M.D.

"GENEALOGIST" writes: Details about Thomas Bill, physician to Henry VIII and Edward VI, "in addition to those recorded in Munk in the *Roll of the Royal College of Physicians*," were given in the *British Medical Journal* of Aug. 18, 1945 (p. 228), and can now be supplemented by reference to Cusson's *History of Hertfordshire* (Odsey volume), according to which the earliest mention of any of the Bill family at Ashwell is that of Christiana Bill, who was assessed towards a subsidy in 1307. The next mention is of the grandfather, Christian name not given, and the father, Thomas, both of Ashwell, of John Bill, draper, in his will dated Aug. 31 and proved Oct. 26, 1503. John and his wife Agnes had one son, also called John, alive in 1524, who married one Margaret, alive in 1551, and had three sons and two daughters: (1) John, the eldest son, a lawyer and probably King's Serjeant, who married twice, first wife dead by 1557, name not given, by whom he had descendants, and second wife Susan Samwell, without issue; (2) Thomas, the subject of these notes; (3) William, Dean of Westminster, who died without issue; (4) Mary, alive in 1558; and (5) a daughter, name not given, married to Thomas Gosnold, also alive in 1558. Thomas Bill, the physician, was M.D.Pavia before 1533 and was incorporated at Cambridge in 1534. His will is dated June 1, 1551, and was proved on Feb. 23, 1552. He married Agnes, daughter of John Theobald, of Seale, Kent, by whom he had Margaret, sole daughter and heir, who married James Haydock, of Graywell, Southamptonshire, by whom she had a family. Agnes Theobald's second husband was Percival Smallpage, and her third Bernard Randolph. Cusson gives the Bill arms: "Ermine; two Bills in a saltire proper; on a Chief azure, between two Pelicans' heads erased argent, vulning themselves, a Pale of the last, charged with a Rose gules"; and the crest: "A Pelican's Head erased, vulning itself as in the Arms." The bills, a canting device, are war weapons, and "vulning" means "wounding," an allusion to the legend that pelicans drew blood from their breasts to feed their young.

Sir Arthur S. MacNalty's presidential address to the History Section of the Royal Society of Medicine on "The Influence of Medical Poets on English Poetry" has been published in full in the June issue of the *Poetry Review*. A limited number of copies (2s.) may be had from the secretary, the Poetry Society, 33, Portman Square, W.1.

LONDON

SATURDAY JULY 6 1946

THE NUTRITIVE VALUE OF BREAD

The National loaf has darkened in colour and dwindled in size, and bread and flour are now to be rationed. At the present critical time informed medical opinion is necessary both to prevent undue dismay among the general public and to counteract any possible complacency among those in authority. It is fortunate, therefore, that the Nutrition Society should recently have published a full account¹ of its important conference in February, 1945, on "Factors Affecting the Nutritive Value of Bread as Human Food."

Judged solely on its content of nutrients, brown wholemeal flour, in which 100% of the grain is "extracted," is much superior to white flour, in which as little as 70% of the grain may be used. McCance has compared the amounts of nutrients present in the whole wheat grain with those found in the central portion of its endosperm, from which the whitest fraction of flour is derived, and his data leave no room for doubt. Thus the protein contents of the whole grain and the endosperm are given as 8.9% and 8.1% respectively, fat 2.2% and 0.7%, phosphorus 311 and 59 mg.%, iron 3 and 0.5 mg.%, vitamin B₁ 1.6 and 0.1 i.u. per g., riboflavin 1.5 and 0.4 µg. per g., and nicotinic acid 42 and 5 µg. per g. Only in carbohydrates does the endosperm surpass the whole wheat, containing 75.8%, as against 66.8%. Similarly the amounts of nutrients in intermediate grades of flour may be correlated with the percentage of the whole grain which is included. Thus the present light-brown flour of 90% extraction is superior to the 85%, 82½%, and 80% broken-white flours which we had in the less hungry days during and just after the war.

In general the amounts of vitamins and minerals decrease steadily with reduced rates of extraction, until, according to Kodicek, a minimum is reached at about 70%. The different nutrients, however, are present in widely varying concentrations in different parts of the "offals." As a result the amounts of individual factors in flours of different extractions do not run quite parallel. Because the scutellum is very rich in vitamin B₁, flour of 85% extraction milled to contain this fraction is little inferior to wholemeal in its vitamin B₁ content. Copping gives values of 1.40, 1.15, and 0.35 i.u. per g. for wholemeal, 85%, and 73% extraction flours respectively.

The nutrient contents of flours, however, represent but part of the story. Many people prefer the neutral taste of white bread to the slightly bitter taste of brown. The texture of brown bread often tends to be harsh. A high proportion of indigestible fibre may cause diarrhoea in sensitive persons, while the heavy manual worker has to eat a greater bulk of brown bread than of white to satisfy

his heavy calorific demands. The superiority of high extraction flour in phosphorus, moreover, may actually be a disadvantage. According to McCance about 60% of this element in wholemeal flour is present in the form of phytate, which might be regarded as a potential cause of rickets.

Arguments for high- and low-extraction flour were thoroughly sifted at the 1945 conference, and many nutritionists agreed that a wise choice had been made in selecting the 85% extraction flour which served so well for a long period during the war. It combined light colour, good taste, and low roughage, with a vitamin B₁ content little inferior to that of wholemeal. Reasonable amounts of other vitamins and minerals were present, any deficiency in the latter respect being readily adjusted by adding calcium carbonate. The action of the Government when, at the time of the conference, it had reduced the rate of flour extraction to below 85% was strongly criticized by McCance and others interested in wheat as food for human beings. Pig and poultry keepers, and to a less extent dairy farmers, were more inclined to rejoice, since the rejection of a highly nutritive wheat fraction from the human loaf raised hopes of less precarious feeding for farm animals. If the National loaf was less pleasing to nutritionists, at least the prospects for eggs and bacon were improved. During the present year, however, the shortage or dislocation in world wheat supplies has caused fundamental changes in official policy. It is essential, we are told, to spare food for Germans and Indians, who are worse off than ourselves. The extraction rate has therefore been raised from about 80% to 90%, which means roughly that, for every eight loaves we eat, one loaf can be spared for use elsewhere. On the other hand, wheat offals have been cut from 20% to 10%, which means that our farm animals will have only about half their previous supplies of food from this source. Fortunately the new 90% loaf, if uninviting to many palates, is richer in nutrients than the loaf it replaces. We shall not starve. But cakes and pastries, if any, will become even more austere, and with a declining animal population the so-called protective foods will probably become more scarce than ever. The new Minister of Food, therefore, has taken over the reins of office at a most serious juncture. While all will hope that he may realize his ambition to introduce a little more variety into our diet, it is difficult to see from where that variety is to come: not everyone is enthusiastic over the prospect of having more dried egg.

PENAL JURISDICTION OF THE G.M.C.

In May, 1945, the General Medical Council, after a long hearing to which the public were not admitted, erased from the *Medical Register* the name of Dr. Arthur Henry Hennessy, a general practitioner of Sanderstead. The charges were that on Sept. 26, 1944, he had attempted to commit adultery with an unnamed woman patient and had indecently assaulted her. Dr. Hennessy had no right of appeal against this decision, but last April he sued in the High Court for slander Miss Irene Boyanton, of Sanderstead, the patient who had accused him of assaulting her.

¹ *Proc. Nut. Soc.*, 1946, 4, No. 1, 1-50. See also *British Medical Journal*, 1945, 1, 379.

He showed that since the G.M.C. hearing she had alleged to two persons in the neighbourhood that he had made love to her and criminally assaulted her in his surgery on Sept. 26, 1944—the allegations which she had made before the Council. He called certain evidence which (for reasons which did not appear) had not been before the Council. Mr. Justice Charles said in his judgment¹ that he utterly disbelieved Miss Boyanton's story of the assault and was satisfied that she had lied in uttering the slanders and in saying, as she had, that Dr. Hennessy had committed adultery with her regularly. He found it difficult to believe that if the Council had had the fresh evidence before them they would not have believed it in preference to that of Miss Boyanton, for she patently lied. In this shocking case there had been obvious slanders, meant to damage and damaging, spoken by a woman who had shown herself a willing and ready perjurer. The Council, in the absence of adequate evidence, had accepted her story and struck this wretched man off the *Register*. The slanders, for which he was awarded £2,000 damages, with costs and an injunction against repetition, were utterly and absolutely untrue, and he was hopeful that the G.M.C. would see their way to reinstating Dr. Hennessy, for in the absence at their proceedings of the evidence he had had before him there had been a gross miscarriage of justice. He offered to communicate with the Council, an offer which Dr. Hennessy's counsel gratefully accepted.

This case brings into clearer prominence than has any other of recent years the Council's defects as a disciplinary tribunal. No blame whatever attaches to the members of the Council for these defects; they are inherent in its statutory constitution. As Mr. Justice Humphreys remarked in the Spackman case, the Council is a domestic forum left to manage its own affairs as it considers best in the interests of the profession. It is not bound by rules of evidence; it has no power to administer an oath or to compel the attendance of witnesses. Its rules permit the reception of written depositions or statements as well as of oral evidence. In short, his Lordship said, the Council is free to adopt its own procedure and to decide on its own methods of proof so long as it obeys the dictates of natural justice. With all respect to so great a judicial authority, surely such cases as this show clearly that freedom is just what the Council does not possess. Because it cannot compel witnesses to attend, nor to take the oath, it has to put up with inferior and often biased evidence, especially in cases in which the complainant is actuated by spite and a desire for private vengeance. To combat the allegations against him the doctor can bring only such witnesses as he can persuade to attend, and the expense of bringing them and of maintaining them during their stay in London falls entirely on him—unless he is defended by a defence society. If he is condemned in these unsatisfactory circumstances he has no appeal. Surely the fact that the Council is a domestic tribunal does not justify its being forced to conduct its disciplinary duties in this manner. A doctor's livelihood is at least as important as any of the issues tried before civil courts, in which evidence is given on oath and before which witnesses can be compelled to attend.

Now that radical reforms in medical practice are about to be enacted, the statutes governing the General Medical Council will doubtless be drastically revised. The Council itself is in fact deliberating on the changes which would in its opinion be desirable in its own constitution. A committee of the Council of the B.M.A. is investigating the composition, functions, and procedure of the G.M.C. as part of a review of the working of the Medical Acts. In this issue too we publish (p. 21) a carefully considered memorandum which has been drawn up by the medical defence societies. A new Medical Act should clearly bring the Council, as a disciplinary body, into line with other domestic tribunals, particularly the Disciplinary Committee of the Law Society, which have been set up in more recent years. It should have power to compel witnesses to appear before it, to oblige them to take the oath, and to award costs against an unsuccessful party. Strong argument could also be adduced in favour of entrusting the hearing of penal cases to a committee, perhaps with a legal chairman. Finally, an aggrieved respondent should be entitled to move the High Court to re-hear the case against him. An appeal to the Court is open to a solicitor or to a dentist; there seems no reason in logic or justice for denying it to a doctor. By good fortune in Dr. Hennessy's case the time between the High Court's finding and the Council's recognition of it was relatively short. If, however, the action had been tried just after the May meeting instead of before it Dr. Hennessy would have had to remain unregistered until the meeting of the Council in late November, unless a special meeting had been convened at a cost of some hundreds of pounds. A right of appeal, with power in the Court to restore a name by order, would avert not only miscarriages of justice but also regrettable delay between the clearing of a doctor's name and his reinstatement.

PROBLEM OF HAEMOPHILIA

Whatever success has been achieved by local treatment of accessible bleeding areas, and however this may be improved by fibrin dressings and more potent thrombolytic preparations, only prophylaxis can make the life of the haemophilic relatively normal. Crippling joint-changes, internal haemorrhages, and constant anxiety can only be avoided if the patient's clotting function is brought within normal limits and kept there. In this respect a line of approach that began forty years ago is becoming promising. In 1906 Weil² claimed that the injection of normal human serum was of benefit in haemophilia. Other workers were not so successful, and attempts to improve the original method by using more specific coagulant fractions of blood such as platelet extracts, resulted in failure. Ten years later, however, Addis³ and Minot and Lee⁴ showed that the intravenous injection of serum, or of whole blood shortened the clotting time of haemophilic patients. Blood transfusion became the accepted, and indeed the only reliable, form of general treatment, though its effect was transitory. Then in 1937 Patek and Taylor⁵ demonstrated that the anti-haemophilic activity of normal blood resides in the cell-free globulin fraction of the plasma. The corresponding fraction of haemophilic plasma had no such activity, so that it appeared that some unknown factor

⁵ J. clin. Invest., 1937, 16, 113.

¹ Times, April 13; British Medical Journal, April 27, p. 665.

present in normal plasma, was absent or inactive in haemophilia.

During the war the fractionation of human plasma on a large scale was developed by Cohn and his associates, and in consequence a number of subfractions of normal human globulin have been available for investigation by American workers. Taylor⁶ and Minot⁷ have made a careful examination of the anti-haemophilic activity of a large number of such fractions. Their work reveals that this activity does not depend on the fibrinogen thrombin or prothrombin content of the fractions, nor on their ability to develop fibrinolytic activity after treatment with chloroform. This latter observation is of importance since Tagnon⁸ observed that haemophilic plasma is deficient in this ability, and it might appear that the fibrinolytic enzyme of plasma has a place in normal coagulation. Unless the classical theory of blood coagulation is to be abandoned, the evidence suggests that it is the thrombokinas of normal plasma which is being studied; and which is reduced or inactive in haemophilia. The investigation may, perhaps, be taken a stage further by the work of Tocantins⁹, demonstrating an increased anti-thrombokinas activity in haemophilia, which may explain the results of other workers. This is probably the first positive finding of importance in research on haemophilia. Such an anti-kinase might be expected to be anti-fibrinolytic also, since Macfarlane and Pilling¹⁰ have shown that thrombokinas and fibrinolysin may be inhibited by the same substances. Interest should centre now on the inhibitor systems in blood coagulation. It is the concept of a constantly operating dynamic equilibrium, between enzymes on the one hand and inhibitors on the other, which is most likely to resolve the problems of coagulation in general and of haemophilia in particular.

As to the practical application of this work, too much must not be expected. The activity of whole blood has been concentrated into a smaller volume by plasma fractionation, but that is all; 200 mg. of active protein now have the same effect as 100 ml. of whole blood, an effect that only lasts 24 to 48 hours. Future work may reduce the effective dose still further, and regular injections may keep the patient's clotting time below the danger level. But it must be remembered that haemophilia is not a deficiency disease; it is an inherited state of disordered physiology. It is as natural for the clotting time to be long in haemophilia as for it to be short in normal people. The haemophilic system may react to attempts to alter its clotting equilibrium by compensatory processes rendering the introduction of foreign substances useless or even harmful.

MANGANESE PNEUMONITIS

Chronic manganese poisoning was first described in 1837 by Couper,¹¹ and since that time some 353 cases have been reported. Manganese appears to be an essential substance in plant and animal nutrition. It occurs in nature as the oxide in the ores, pyrolusite, braunite, hausmanite, and manganite, which are found in Russia, India, the Gold Coast of Africa, Brazil, the United States, and Cuba. Its most important alloys are spiegeleisen and ferro-manganese, but silico-manganese and silico-spiegel are employed in certain grades of steel. Manganese bronze resists corrosion and is used for marine construction and mining machinery. Manganese is also alloyed with aluminium, tin, arsenic, antimony, bismuth, and boron. The oxide is used in bleaching glass, the chloride in dyeing, the sulphate in calico printing, and the persulphate as an oxidation agent in making

organic products. Manganates and permanganates are used for preserving wood, for bleaching textile fibres, and for disinfecting and oxidizing purposes.

In chronic poisoning the commonest pathological changes affect the central nervous system and result in the Parkinsonian syndrome. Accounts of the condition have mostly come from Europe, but cases have been reported in England by Charles,¹² and by Owen and Cohen,¹³ and recently a full review has been produced by Fairhall and Neal¹⁴ in the United States. As long ago as 1921 Brezina¹⁵ drew attention to the relationship between manganese and pneumonia; he reported that five out of ten men working in a pyrolusite mill had died of pneumonia in a period of two years. Baader¹⁶ ascribed to manganese the high incidence of pneumonia among workers making dry-battery cells. Elstad¹⁷ in Norway observed that the erection of an electrical plant for smelting manganese at Sanda was followed by a tenfold increase in the mortality rate for pneumonia in that area; a pall of smoke containing manganese oxide with particles of less than 5 μ overhung the town. Immediately before the war Buttner¹⁸ reported that men working in a Rhenish pyrolusite mine had an average pneumonia rate of 17 per 1,000 with an average death rate of 6.3 per 1,000, as compared with a pneumonia rate of 0.54 per 1,000 in a control group from Leipzig.

Lloyd-Davies¹⁹ has now recorded his observations on men employed in the manufacture of potassium permanganate and exposed to the inhalation of dust containing manganese dioxide and the higher oxides of manganese, the manganese content of the atmospheric dust being between 41 and 66%; practically all the particles were below 1 μ in size, and 80% were below 0.2 μ . This group of men, numbering from 40 to 124, had an incidence of pneumonia which varied from 15 to 63 per 1,000 in the period 1938 to 1945, compared with an average of 0.73 per 1,000 for the same period among male members of Boots Health Insurance Society. Nasopharyngeal catarrh was common, and attacks of bronchitis were frequent; these always subsided after removal from exposure. The pneumonia which occurred did not differ clinically from that which may develop in any individual, and Lloyd-Davies illustrates his paper with radiographs showing upper-lobe consolidation which resolved in nine weeks. He suggests, however, that the temperature and general condition of the patient respond more slowly than usual to sulphonamides. No permanent pulmonary changes were observed either clinically or radiologically.

Animal experiments in which mice were exposed to manganese dust were complicated by the obvious toxic effect of the manganese, but the histological effects on the lungs were uniform and striking. The changes were dependent on the length of exposure, and varied from slight mononuclear infiltration to intense mononuclear interstitial infiltration with many dust-laden cells, progressing finally to consolidation, including haemorrhagic areas, leading to complete disorganization of the lung structure. The changes were most marked around the bronchi; cells lining the bronchi were swollen and had undergone hydropic change. Lloyd-Davies thinks the manganese has a direct influence on the cells of the bronchial and alveolar epithelium. The presence of dust cells, even though few, suggests that the dust is phagocytized, but it is probable that after absorption the phagocytic cells are killed. Either before or after absorption manganese would appear to

have a specific action, causing intense mononuclear proliferation and infiltration, and being sufficient to cause consolidation of the lung with necrosis and haemorrhage.

TUBERCULOSIS UNDER THE BILL

Controversy over the general aspects of the Health Service Bill has obscured the question of what the Minister intends for the tuberculosis services. Indeed, the name of this disease does not appear anywhere in the text of the Bill. This is perhaps explainable in a measure purporting to deal with health rather than disease, and the future of our tuberculosis services when the Bill becomes law is at present a matter for deduction and conjecture. From what can only be guessed, or read between the lines, anticipations on the subject are not free from misgiving. Presumably the treatment of cases of pulmonary tuberculosis, which form a majority of the tuberculous population, will be in the hands of chest specialists at the new regional clinics and hospitals. In so far as the tuberculosis officer will be considered a chest specialist, and presumably have more hospital beds and clinical facilities, this change is to the good. But if at the same time he is not to have complete charge of the tuberculous patient, more will be lost than gained. When one inquires about the environmental aspects of the tuberculous patient's care, the control of his home surroundings, and his rehabilitation towards normal life, these are found to come under the local health authority. Further, industrial re-employment is the concern of the Ministry of Labour. To make a fourth branch of this inconvenient division of the tuberculosis patient's interests, we have the unwelcome news that the treatment allowances (266/T) are to be abolished. It would seem that the tuberculosis service of Great Britain, which led the way in 1912 and still leads the world, is to be broken up into fragments. This view is expressed in an article in the June issue of the *N.A.P.T. Bulletin* entitled "Disintegration"; it is also the opinion of Dr. Frank Ridehalgh, tuberculosis officer for the City of Leeds, writing in the *Times* on June 11, of the Joint Tuberculosis Council, and of a large number of tuberculosis officers. Mr. Bevan has promised or threatened a third Bill—additional to the Health Service and National Insurance Bills—to deal with Poor Law and to clear up remnants of socio-medical legislation, and until this new measure emerges the social welfare of the tuberculosis patient is not provided for. If these deductions from the text of the Health Service Bill are incorrect, would it not be well for the Minister to show what he has in mind for the tuberculosis service of the country?

MATAS OPERATION FOR TRAUMATIC ANEURYSM

"The report of the first patient treated by endo-aneurysmorrhaphy was made by Dr. Rudolf Matas in the *Philadelphia Medical News*, October 27, 1888. In the 57 years which have intervened since that memorable publication no alterations in the technique of the procedure other than minor niceties have been made. Few operations have stood this test of time, and none has had a more profound effect upon the surgery of blood vessels." Thus Elkin¹ begins an account of 106 false aneurysms treated by operation during thirty months; in 61 the Matas procedure was employed. There were no deaths, no recurrences, and no instance of gangrene.

Elkin's warm advocacy of the method stresses its simplicity; his results indicate its effectiveness. The problem that confronts the surgeon in these cases is well shown by the account of Matas's original case. A young negro had

a large traumatic aneurysm of the brachial artery, which had recurred after combined proximal and distal ligation of the main artery. When Matas exposed it at operation he found that the branches of the brachial plexus were so firmly incorporated in its walls that excision was impracticable. Exploration of the interior of the sac revealed three large orifices, corresponding to collateral branches, which had clearly caused the recurrence. Matas realized that the easiest way out of the difficulty was to seal the orifices of these collaterals by suture. This was done with ease and with success. As Elkin states, the Matas endo-aneurysmorrhaphy is simple in conception, and if the principles of its application are borne in mind it is easy to carry out. The seven cases he selects to illustrate his experiences are examples of difficult, and even terrifying, large traumatic aneurysms in the most awkward places.

Before the introduction of the Matas procedure aneurysms were treated by a variety of methods, most of them unsuccessful. Antyllus, a fourth-century surgeon, ligated the vessel above and below the sac, the contents of which were evacuated before applying an astringent or packing; this operation was performed right up to the eighteenth century. In 1710 Anel suggested ligation of the proximal artery close to the sac, but it was chiefly due to the introduction by John Hunter of proximal ligation at a distance from the sac, in order to lessen the risk of gangrene, that the operation of Antyllus was abandoned. The Hunterian ligation was often successful. Its success has been marred, however, by frequent recurrences, the sac being fed through the collateral channels Hunter was so anxious to preserve. Even to-day, with proximal and distal ligation combined with excision of the sac as the method of choice, the simplicity and effectiveness of the Matas operation is quite inadequately appreciated. In those cases with a huge, diffuse, and widely adherent false aneurysmal sac, resulting from gunshot wounds, excision of the sac is always difficult and often dangerous or impossible. It is, therefore, important that the principle of the Matas operation should be widely known and appreciated.

MEDICAL FILM COMMITTEE

The Council of the British Medical Association has set up a committee to inquire into the scope and use of films in postgraduate and undergraduate medical education. Under the chairmanship of Sir Lionel Whitby the committee is composed of the following members: Lord Amulree, Mr. V. Zachary Cope, Dr. A. E. Barclay, Dr. J. A. L. Vaughan Jones, Dr. R. P. St. L. Liston, Dr. B. G. Maegraith, Dr. R. C. MacKeith, Mr. R. L. Newell, Mr. H. Reid, Dr. C. M. Seward, Prof. J. C. Spence, Mr. A. Dickson Wright, and Mr. R. L. Pryer and Mr. S. A. Biggart appointed by the British Medical Students' Association. One of the first tasks of the committee will be to survey the different techniques in which films are employed in other spheres of education. The film was used extensively in Naval, Army, and Air Force training during the war, and the experience in these fields should prove most valuable. The committee will consider how far the lessons learnt can be applied to medicine. Problems of production, distribution, cataloguing, and projection will all have to be studied. It is clear that a vast field for valuable work is opening up.

The Hugh Owen Thomas Memorial Lecture will be delivered by Mr. George Perkins, President of the British Orthopaedic Association, at the Liverpool Medical Institution (114, Mount Pleasant, Liverpool) on Thursday, July 11, at 4 p.m. His subject is "Bone Grafting."

POWERS AND PROCEDURE OF THE GENERAL MEDICAL COUNCIL

A memorandum on Proposed Variation of the Powers and Procedure of the General Medical Council has been drawn up by the Medical Defence Union, Ltd., the London and Counties Medical Protection Society, Ltd., and the Medical and Dental Defence Union of Scotland, Ltd.

Proposals for Reform.

The Councils of the three defence bodies are of opinion that the existing powers and procedure of the G.M.C. require strengthening and amendment to bring them into alignment with modern practice in criminal courts and courts-martial regulated by rules of procedure similar to those of the Disciplinary Committee of the Law Society. Having posed certain questions to and received the opinion of counsel, the societies submit the following decisions for the consideration of the G.M.C., believing that their adoption would redound to the benefit of all concerned.

That the General Medical Council be empowered and required to establish two distinct and separate committees to be known as (a) the Penal Cases Committee and (b) the Disciplinary Tribunal. That a member of the Penal Cases Committee be not eligible to sit as a member of the Disciplinary Tribunal to hear a case that has already been before him as a member of the former committee.

That the Disciplinary Tribunal, sitting with a legal assessor, consist of 7 members drawn from a panel of 12 members elected by and from the G.M.C.; that its quorum consist of 5 members, and that it be vested with the full disciplinary and judicial powers of the G.M.C. That complaints received by the G.M.C. be examined in the first instance by the Penal Cases Committee to determine whether a *prima facie* case exists for reference to the Disciplinary Tribunal for determination.

That the General Medical Council be incompetent to present any case in which a Government Department or a constituent body is the complainant, and that the burden of the presentation of any complaint be undertaken only when the Council is satisfied that justice would be denied in the absence of its intervention. That the initial complaint in all cases, including information laid by a Government Department, be supported by an affidavit or affidavits setting out all material facts. That a copy of the affidavit or affidavits be furnished to the respondent with any request addressed to him to provide a reply and explanation. That the respondent be given not less than four weeks' notice of any inquiry to be held by the Disciplinary Tribunal with discretionary power vesting in the President to extend the time on the receipt of an application to this effect.

That the attendance of witnesses and the production of documents before the Disciplinary Tribunal be enforceable by subpoena. That all evidence before the tribunal be given orally on oath save for good and sufficient reason, except evidence as to character, which may be given in writing. That each party furnish to the other not later than 10 days before the hearing of the case a list of the documents on which they propose to rely. That notice to produce and admit be not permitted.

That the Evidence Act, 1938, be not made applicable to the proceedings of the Disciplinary Tribunal. That the parties be entitled to require the tribunal to subpoena any deponent to an affidavit to give oral evidence. That only those documents which are agreed by the parties and such others as are proved in evidence be placed before the tribunal.

That a summing up by the legal assessor be not required unless it is requested by the Disciplinary Tribunal or one of the parties when in the opinion of that party a point of law is involved. That if and when the legal assessor sums up, he be obliged to do so in the presence of the parties. That the legal assessor be a barrister or a solicitor experienced in the practice of the Courts of Common Law and of not less than 10 years' standing.

That provision be made for a right of appeal to the High Court by the respondent on points of law only. That in the event of an appeal any order for crasure be suspended until after the disposal of the appeal, subject to the appeal being entered within 7 days from the date of the order.

That the Disciplinary Tribunal be empowered (in addition to the present penalty of crasure) to administer other penalties short of crasure—viz., suspension for varying periods or censure of differing degrees. That the tribunal be empowered to award costs against a complainant or respondent and that machinery be established for taxing the costs.

That the General Medical Council be given the power, but not the exclusive power, to conduct prosecutions for infringements of the Medical Act, 1858.

That the words "professional misconduct" be substituted for the words "infamous conduct in a professional respect" and used in the same connexion.

That the rules of procedure relating to penal inquiries be not subject to the approval of a judicial authority.

That the appropriate provision of the Medical Act be amended to permit of the imposition of a maximum penalty of £500 and the alternative of a term of imprisonment for persons convicted of falsely holding themselves out to be registered medical practitioners.

That addition be made to the present protected designations appearing in Section 40 of the Medical Act to embrace abbreviation of recognized medical qualifications, the courtesy title of "Dr." when associated with the healing art, and any other description in common use that is accepted by the public and the profession as indicating that the user is a registered medical practitioner.

SOCIAL SURVEY OF DIPHTHERIA IMMUNIZATION

Diphtheria immunization was recently the subject of an investigation made by the Social Survey for the Ministry of Health. In the course of the inquiry over 2,000 mothers were interviewed. They were a representative sample of mothers of children aged under 16 in England and Wales. The results of the inquiry are given in a report bearing the name of Kathleen Box and issued by the Ministry of Health. (New Series, No. 69.) Among points made are the following:

The Ministry's publicity campaign has had widespread success in persuading parents to have their children immunized, and in bringing to their notice the free immunization scheme. Of the mothers interviewed 81% with one or more children who had passed the first birthday had had at least one child immunized; 84% of the immunized children had been immunized under the local authorities' free scheme, the remaining 16% by private doctors. The two peak ages for immunization were at about the first and fifth birthdays. Of the immunized children 34% were immunized at the suggestion of the school, 19% at the suggestion of a welfare clinic, and 6% and 5% at the suggestion of health visitors and doctors respectively. Of the mothers interviewed 35% had had their children immunized on their own initiative, as a result of hearing about immunization from publicity. Immunization posters had been noticed by 87% of the mothers interviewed, newspaper or magazine publicity by 75%, radio publicity by 50%, and cinema publicity by 40%.

There was no considerable difference between the proportions of immunized children in towns and in rural districts; the proportion was rather lower in the North than in the South. Mothers in the higher education and income groups were slightly ahead of those in the lower groups in having their children immunized. Among interviewed mothers who had not had their children immunized, only 15% said that they did not believe in it. Resistance to immunization came from another 26% on various other grounds, such as that the husband objected, or that the mother feared the child would be hurt or frightened. The largest group of unimmunized children (35% of the total) was accounted for by apathy and ignorance on the part of the mother.

MEDICAL BIRTHDAY HONOURS

A further list of Birthday Honours was published in a *Supplement* to the *London Gazette* on June 24, and included the names of the following members of the medical profession.

O.B.E. (Civil Division)

ARCHIBALD BUCHANAN BARBOUR, M.R.C.S., L.R.C.P., A.F.R.Ae.S., lately Commander and Chief Medical Officer, Air Transport Auxiliary.

JOHN CONSTABLE BROOM, M.D., Acting Director of the Laboratory of Tropical Medicine, Wellcome Research Institution.

Mrs. EVA COTCHING, M.B.E., M.D., lately Deputy Director, Iraq Soldiers', Sailors', and Airmen's Families Association, Palestine.

Surg. Capt. ARCHIBALD FAIRLEY, M.B., Ch.B., R.N.(ret.), Principal Scientific Officer, Chemical Defence Experimental Station, Ministry of Supply.

GEORGE FOGGIN, L.R.C.P.&S.Ed., Principal School Medical Officer, Newcastle-upon-Tyne.

FREDERICK JAMES SIMKIN HALL, M.B., B.S., F.R.C.S.E.D. For services to ships lying off Deal, in the Downs.

ENEAS KENNETH MACKENZIE, M.D., J.P., Chairman, Ross and Cromarty Insurance Committee.

HUBERT TURNER PENN YOUNG, M.B., Ch.B., Medical Officer, H.M. Prison, Wormwood Scrubs.

M.B.E. (Civil Division)

ERIC WILLIAM BINTCLIFFE, M.S., F.R.C.S., Senior Surgeon, Royalwood Hospital, Worcester, Ministry of Pensions.

Mrs. R. C. LANCASTER (Miss RUTH DURY), M.B., Ch.B. In charge of the Military Families Hospital, Rumwood Court, Langley.

ROBERT CATHERWOOD WALLACE, M.B., Ch.B., Admiralty Surgeon and Agent and Medical Officer, R.N. Armament Depot, Crompton.

MACKENZIE INDUSTRIAL HEALTH LECTURE

Dr. Donald Hunter, F.R.C.P., will deliver the Mackenzie Industrial Health Lecture at B.M.A. House on Wednesday, July 24, at 5.45 p.m. The title of the lecture is "Academic Aspects of Industrial Medicine," and admission is by ticket only. The lecture will be confined to persons, lay and medical, who are professionally interested in industrial medicine. Tickets of admission can be obtained from the Secretary, B.M.A. House, Tavistock Square, W.C.1, and early application is requested as the number is limited.

CONSULTANT PAEDIATRICIANS

We print below an abridged version of a document on the appointment of a consultant paediatrician which has been drawn up by the British Paediatric Association, partly as a result of requests from various centres. Copies of the full text may be had from the secretary of the B.P.A., Hospital for Sick Children, Great Ormond Street, London, W.C.1. The suggestions are intended to help centres, other than the main undergraduate teaching schools, where such an appointment is under consideration.

Qualifications for Appointment

A consultant paediatrician should have received his or her paediatric training at an approved children's hospital or children's department of a hospital, and have a minimum of five years' training and experience after qualification. One, preferably the first, year of this period should be spent in an appointment or appointments in adult medicine or surgery. Three years should be devoted to paediatrics, using this term in its widest sense to include all medical work among healthy and sick children, and one year should have been spent working at some allied subject. He should be a Member or Fellow of one of the Royal Colleges of Physicians or hold an approved higher degree in general medicine; the D.C.H. is not essential. He should not engage in general practice.

Standards of Remuneration

These should be based on the assumption that no considerable measure of private practice will be available. In determining standards for a consultant paediatrician, whether part- or whole-time, his services should be valued in the light of the work done and responsibilities assumed, bearing in mind that the care of children involves great responsibility. Travelling expenses in connexion with his work, adequate secretarial and office assistance, and time off to attend meetings of learned societies should be provided.

In his hospital work he should have adequate medical assistance of the type of medical registrars and house-physicians, and these must be taken into account when assessing the requirements and cost of the department. So that the best nursing services may be available the senior nursing staff in the children's department should hold the sick children's nurse's certificate.

Duties of the Consultant

He should have general charge of the children's department of local hospital; act as consultant to the local hospital for infectious diseases; be responsible for care of the newborn in the local maternity department; be available as a consultant for long-stay country hospitals, convalescent homes, and residential schools for defective children; act as a consultant to the School Health Service, the local welfare clinics, the Tuberculosis Service as applied to children, and any other service for children for which the local authority is responsible; be available for domiciliary consultations, as determined by the new Health Bill; and undertake teaching duties for house-physicians, nurses, midwives, health visitors, etc., in close association with the local university department of child health.

The consultant paediatrician should be jointly appointed by the appropriate hospital board and local authority, in consultation with the university of the region, and it would be an advantage to have some external assessors. The emoluments and conditions of work should be made attractive in order that those of high standing may be led to apply.

The report for 1945 of the Kashmir Medical Mission of the Church Missionary Society has been published from Mysore City. Shortage of staff influenced the output of work both in quantity and quality. Dr. Cecil Vosper left for England in June after 33 years of faithful service on the Frontier and in Kashmir, and a tribute to his work and character is paid in the report. One regrettable result of the war has been the impossibility of maintaining adequate repairs and renewals owing to the prohibitive cost, and much new equipment will also be required. The Mission Hospital at Srinagar looks forward to brighter times when full and efficient staffs are again the order of the day. The general survey is signed with the initials of the Rev. K. W. MacKenzie, M.B., superintendent, and non-treasurer and secretary.

Reports of Societies

NUTRITIONAL EXPERIENCES IN P.O.W. CAMPS

A conference of the Nutrition Society on May 18, at the London School of Hygiene and Tropical Medicine, discussed nutritional experiences in prisoner-of-war and internment camps in the Far East.

Dr. P. S. SELWYN-CLARKE, Director of Medical Services, Hong Kong, who acted as chairman, said that during the war the wise guidance of Sir Edward Mellanby and others had prevented malnutrition in Great Britain. Dr. Magee had produced evidence that the children, at least, were better nourished than before the war. The situation in other parts of the world, however, was much less satisfactory. Rapidly increasing populations had to subsist on the products of cultivated areas which dwindled as the result of soil erosion. As a result bad harvests, combined with shortage of shipping, had led to the present crisis, in which death by starvation threatened about 150 million people. It was therefore essential to have expert advice on how best to use available food supplies. Nutritional Research Committees had already been established in many colonies, and he was authorized to announce that a control Colonial Nutrition Research Committee would shortly be set up to advise the Colonial Secretary.

Deficiency diseases appearing in prison camps might presumably be taken as a rough index of those likely to occur in the population of the surrounding territory. The present meeting, therefore, might well be regarded as a regional conference on general nutritional problems in the South-West Pacific area. Undoubtedly, however, complications in the interpretation of data arose from the special conditions of life in individual camps. Thus, great variations existed in regard to climate, hygiene, housing, clothing, and water supplies, and in the facilities for sanitation, washing, cooking, and recreation.

He had been impressed by the number of syndromes, presumably of nutritional origin, which bore a distinct resemblance, although incomplete, to conditions met with in general medicine. Thus in a camp on the Kowloon Peninsula he had observed several cases which might have been diagnosed as Paterson's syndrome, but in which koilonychia and hypochromic anaemia were absent. In Hong Kong Major Harrison saw several cases of a syndrome resembling subacute combined degeneration of the cord, but without extensor plantar response. Several minor points presented interesting problems. It was difficult to understand why young women should digest rice much better than young men. An explanation had still to be found for the violet hallucinations which troubled sufferers from the amblyopia which appeared as a complication to frank vitamin B₁ deficiency when they attempted to read.

Formosa P.O.W. Camps

Lieut.-Col. J. BENNET, R.A.M.C., said that in prisoner-of-war camps in Formosa it was difficult to decide to what extent the incidence of deficiency diseases could be attributed to the somewhat defective diet. Environmental stress, compulsory hard labour, a high incidence of malaria and other infectious diseases, combined often with the after-effects of transport by sea under appalling conditions, all contributed to a highly complex picture of ill-health. A diet consisting mainly of unpolished rice was freely eaten by men who had a deep elemental fear of starvation. Large amounts of vegetables of poor nutritive quality and coarse texture were also consumed. The resulting intestinal irritation caused diarrhoea, which undermined health and led to a high incidence of nutritional oedema.

In some camps the prevailing oedema was classified as beriberi, but this diagnosis disregarded the outstanding features, which were its soft pitting character and the effect of posture in determining its distribution. Some indication of vitamin B₁ deficiency, however, was given by the occurrence of neuritis in the later years of captivity, although the features were not those usually found in beriberi. The bones and joints ached severely, and there were cramping sensations in the feet. Often the nerve cords were thickened and tender. Retrobulbar neuropathy was another common abnormality. The complete picture of the sprue syndrome was rare, although some cases will

rhoea showed early changes in the tongue. Large blooders sometimes formed in the mouth, even in men who were arently fit.

isoners who were expected to work received about 2,500 to 0 calories daily, but when officers were excused work their ke was reduced to 1,770 calories. It seemed probable that diet would have maintained a reasonable state of health in absence of "conditioning" factors, such as overwork, tion, and diarrhoea.

Interned Civilians in Hong Kong

r. D. A. SMITH described conditions in a civilian internment p in Hong Kong which housed about 1,300 men, 900 en, and 300 children. The main foodstuff was highly milled e rice, of poor quality, and usually infested with weevils. ration allowed by the Japanese also included water-buffalo in 1942, but this was later replaced by fish, which during last two years was salted and supplied only every other th. A little arachis oil and some salt were allowed. ese cabbage, water spinach, chrysanthemum and sweet to tops, and gourds were the main vegetables. The diet calculated to be low in all nutrients except carotene, min C, and iron. Some food was fortunately obtained from r sources, and included beans, wheat bran, and rice polish- purchased from the local Red Cross organization occa- al International Red Cross parcels, and the produce of p gardens.

he first effect of poor diet was loss in weight. After the few months the body seemed to adjust itself to the new e of nutrition. A lowered metabolic rate was accompanied bradycardia, hypotension, weakness, undue liability to ue, dizziness, and fainting. About 90 days after capture beriberi first appeared, and throughout the whole period cases occurred. The condition could readily be cured with talline aneurin, preferably given by injection. Although incidence of beriberi rose in warm weather, the main factor eciding its incidence was the amount of vitamin B in the at different periods. A high incidence could be expected n the daily intake fell below 0.25 mg. per 1,000 non-fat ries. At about the same time numerous cases of oedema e noticed which were not associated with neuritis. This dition did not respond to aneurin, and was presumably due rotein deficiency. Features of pellagra, usually including sitis and blood-blisters in the buccal mucosa, were found 157 cases, but the typical brown pigmentation was seldom erved. "An "ora-genital syndrome," with angular stomatitis genital dermatitis as its main characteristics, was frequently ountered, and was ascribed to deficiency of riboflavin. There e 55 cases of tropical macrocytic anaemia. Other lesions e retrobulbar neuropathy, which failed to respond to such ry treatment as was available in the camp; and "electric," which were not cured by aneurin but improved gradually n beans, wheat bran, and rice polishings were given.

Internees at Singapore

rof. R. G. SCOTT MACGREGOR recounted his experiences in civilian camp at Singapore. At Changi prison 3,000 inter- s were at first housed in accommodation designed for 600, in 1944 the camp was moved to primitive huts on the Sime d. The Japanese allowed the camp to look after its own al organization, and a Medical Reference Committee was ned which met at weekly intervals for three years to take e of nutritional matters. The diet allowed by the Japanese much the same as in Hong Kong, but the rice was often olished. Red Cross facilities were not freely allowed, but committee was able to arrange for the purchase of supple- tary foodstuffs, such as rice polishings, ground nuts, and en dhall, through a neutral agent. The diet provided 2,000 ories daily for healthy men, with less for invalids. Women l children received only about 1,000 calories. In order to rt the ill effects of periods during which the food supplied the Japanese was worse than usual the committee showed at resource in the provision and issue of supplements. Thus reu-palm oil was distributed during the early months when lack of vegetables brought danger of deficiency of vitamin A. During periods when the Japanese were supplying unpolished rice improvised drying plant was put into service. This allowed the storage of rice polishings in stable form so that they might

be issued when beriberi was threatened through a change of the ration to polished rice. A procedure was even devised for the extraction of salt from sea water at times when the salt ration was low, but the injudicious use of salt sometimes increased the tendency to oedema.

Probably as a result of the committee's careful planning, the incidence of deficiency diseases was comparatively light. Although the average age of the internees was 44, the mortality was under 10%. Nevertheless, losses of 2 st. (12.7 kg.) in weight, and 1/2 to 1 in. (1.25 to 2.5 cm.) in height, were common. Only 30 cases of beriberi occurred in the early stages of internment, and there were no further cases except for a few in 1945. There was an outbreak of retrobulbar neuropathy in 1943, and of pellagra in 1944.

Drs. R. C. BURGESS and E. K. CRUICKSHANK both spoke about malnutrition in the military camp at Singapore. Although the calorie intake was reasonably adequate, there was, as in other camps, a serious deficiency of protein and of vitamins of the B complex. The incidence of beriberi, which could clearly be correlated with periods when the vitamin B₁ intake was low, rose to a high level two months after capture in 1942, but was very low when an improved diet was received during 1943. Later, however, deterioration of food supplies caused a steady rise in incidence to a peak in 1945. To keep the vitamin B₁ intake as high as possible steps were taken to ensure that losses involved in washing and cooking rice should be minimized. At one time yeast was grown as a source of vitamin B₁, but the specimens obtained proved to be of little value. The incidence of conditions due to deficiency of the vitamin B₂ complex, including mouth lesions, aching feet, and scrotal dermatitis, were parallel with low levels in the riboflavin intake, but apparently not related to the estimated nicotinic acid level. The incidence of keratitis followed most other deficiency conditions fairly closely, but retrobulbar neuritis was slow in appearing.

Prevention of lesions due to deficiency of the vitamin B₂ complex was effected by increasing the intake of green vegetables to about 180 g. per day. Protein deficiency remained severe, as indicated by the very low serum value of 4.7%, estimated immediately after liberation. One of the most distressing effects of malnutrition, however, was undoubtedly aching feet, which kept the sufferers awake at night. Some tried to find relief by an endless walk round their sleeping-quarters. Others wore several pairs of socks, or knelt in a bent-up attitude, squeezing their feet with their hands.

Effects on Women and Children

Miss E. M. M. HUME read a paper contributed by Dr. CICELY WILLIAMS which dealt with the nutritional conditions among women and children interned in Singapore. After the capitulation a motley group, made up of professional women, nurses, and the wives of British civilians or prisoners of war, some European, some native, and some Eurasian, was paraded all day in the sun at the centre of the town, before being marched 6 miles (9.6 km.) to houses in Katong. Here they were kept for three weeks, with little food and no sanitation, before transfer to Changi prison. Although the women were kept in quarters separate from the men, information and food were exchanged, and the women had the benefit of advice from the Medical Reference Committee. On the whole the women, with their lower metabolic rate, withstood dietary deprivation better than men, but there was great individual variation. Some native women, accustomed to rice, actually put on weight during the first stages of internment. The coarse bulky nature of the diet, however, gave some Europeans diarrhoea. Apart from a few cases of frank deficiency diseases, the main physical disabilities were giddiness, cessation of menstruation, and nocturnal diuresis. Hunger was not only distressing as a sensation but was generally accompanied by feelings of insecurity and anxiety, and longings for rich food. In the early months the nights were perpetually disturbed by overcrowding, crying babies, prowling sentries, women having nightmares, quarrels among cell mates, and by attacks of enteritis, indigestion, and anxieties. All these factors tended to settle with familiarity and conditioning, but even when fluids were avoided during the latter part of the day the nocturnal diuresis persisted, in most cases until some weeks after liberation. The children were undersized, but most of them were otherwise normal. It

is highly satisfactory that in 300 children, including 20 babies born in the camp, only 2 deaths occurred, and these were in babies sick before internment.

Dr. J. V. LANDOR discussed the pathology of the conditions occurring in prison camps. He mentioned in particular the occurrence of purplish areas, often following injury, which he ascribed to infection with diphtheria bacilli.

Dr. SELWYN CLARKE, in thanking the authors for their contributions, emphasized the great importance of the information which they had made available. It was most desirable that all the data should be published in adequate detail, and there seemed to be ample material for a further conference on the same subject.

Correspondence

Reduction in Rationed Foods

SIR,—The Executive Committee of the Guildford Division has instructed me to write you upon the question of further reduction in rationed foodstuffs.

It was strongly held that the Government should have before it solemn warning from actively practising members of the profession that the state of the national health, so far from being better than ever, is only fortuitously being maintained; that the war weariness and fall in production in essential heavy industries is a better index of adequacy of nourishment of the country as a whole than are Governmentally collected statistics. It was held that the country had been most fortunate to have escaped a major epidemic so far, and that the cuts in protective foods and first-class proteins were likely to lead to a serious diminution of the mass resistance to epidemic disease.

We wish to record our whole-hearted disagreement with the predicted "cuts," in particular, in regard to fats and meat rations. We would strongly urge the necessity of obtaining at any cost a more adequate supply of these essential commodities, and then we are strongly of the view that both resistance to disease and the will to work hard for national recovery would be materially increased.—I am, etc.,

DAVID HALER,
Hon. Sec., Guildford Division.

West Byfleet.

Migrainous, Ciliary, and Post-traumatic Headaches

SIR,—Mr. Cecil Tivy (June 22, p. 964) refers to my article (May 18, p. 754) as being open to severe criticism from at least one point of view, and he goes on to say that I talk light-heartedly of the loss of corneal reflex after my injections. I find I made two references to the corneal reflex, the first when I described the effect of a small injection, leaving loss of sharpness to pinprick and loss of the corneal reflex, or even complete analgesia (p. 755). Mr. Tivy apparently does not distinguish between analgesia and complete anaesthesia, for he continues that I surely must be aware that the correct description would be "complete loss of corneal sensation, with its attendant loss of trophic nerve supply." For his information I may say that analgesia means loss of sharpness, and complete anaesthesia means not only loss to pain but to touch and pressure. I referred to diminished corneal reflex, with light analgesia of the ophthalmic and maxillary divisions, in Case 3, a public schoolboy, whom I injected with only 3 mins. (0.18 ml.) of alcohol. If this is being light-hearted I will not quarrel with the term.

I never touch the cornea if I can help it; the ciliary reflex is usually sufficient, but a better test for comparison of the two sides is to prick lightly the inner canthus with a pin; this seems to me to be the most sensitive part of the face. The after-care of the cornea is most important when the ophthalmic division is anaesthetic, but in the very large majority, if the patients carry out my instructions to instil a drop of liquid paraffin three times daily, and wear a shaped "celloidin" shade, made specially for me by Solport Bros., during the day-time for three weeks, only a few give trouble. It is the eyes with chronic conjunctival catarrh which are most likely to go wrong, quite certainly if trachoma is present. Even then,

atropine and eye-baths and careful fomentations, with rest in bed, may avert tarsorrhaphy. Over 20 years ago, when discussing the incidence of keratitis with Harvey Cushing, when he came to see me do a ganglion injection at Maida Vale, he agreed with me that eyes varied very much in their reaction, that some kept normal even if no care were taken, yet others in spite of careful treatment might develop keratitis.

A point I am always careful to inquire into is the vision of the eye on the non-affected side, for should that be useless, not more than 3 mins. alcohol should be used within the ganglion, and then only in cases of extreme severity of pain affecting the ophthalmic division.

As regards follow-up of cases, which Mr. Tivy suggests I omit, he can scarcely have read my article carefully, and I may add that I have had in addition many scores of letters sent spontaneously from grateful patients, often many years after treatment. He says he is all too well aware of the number of people who suffer from intractable headaches, and of the amount of misery they suffer, and yet he expresses grave doubts whether a Gasserian operation is justifiable.—I am, etc.,

London, W.1

WILFRED HARRIS.

Lumbo-sacral Root Pain

SIR,—Analysis of the article by Dr. J. MacD. Holmes and Mr. B. R. Sworn (June 22, p. 946) leaves me confused as to the need and results of their operative measures and methods employed. They state: "We have therefore made a complete clinical and radiological examination of all our patients with sciatica, including lumbar puncture with manometry and examination of the cerebrospinal fluid. . . . If operation has seemed necessary . . . myelography has been carried out and operation has been performed" if myelography has been positive and in some cases even if negative. Of the 50 cases operated upon "in which we had made a confident diagnosis of a lesion," no lesion was found in 10 (20%), but "a considerable measure of relief followed operation" in spite of this. They suggest conservatism in their methods by the statement, "Laminectomy may be necessary for extensive lesions, but in most cases of disk rupture we have used the interlaminar approach, usually combined with removal of the lower border of the upper lamina," yet in the history of the only case which they cite they state "the fourth and fifth lumbar laminae were removed" and still no lesion was found. With such surgical trauma I find it difficult to believe, "at least a considerable measure of relief followed operation—in spite of the fact that in some of them we had found no visible lesion" and "in the cases with negative myelograms no appreciable relief followed operation, but no patient was worse."

Inman and Saunders (*Radiology*, June, 1942, p. 669) have recorded: "It is disappointing, however, in spite of initial brilliant post-operative results, to find a certain proportion of cases presenting a residual of painful symptoms." They emphasize a similar injury to the ligaments around the interpeduncular foramen which is not modified by removal of the disk remnants, and in support of this they quote that the State Corporation Fund of California reports "compensable disability in 100% of patients operated upon for disk injuries." A. Oppenheimer (*New Engl. J. Med.*, Jan. 27, 1944, p. 95), reporting on a study of 826 cases, states, "Most of the clinical manifestations are caused by those secondary alterations rather than the primary disk lesion. Even rupture of the disk is not an invariable exception to this rule." It has been proved by more than one observer that positive myelography may not be supported by operative findings, yet negative myelography is by no means infallible. Neither it nor laminectomy are without the risk of serious damage to the patient.

Presumably most of this work of Holmes and Sworn has been done within a relatively short time. But my experience is that patients who have suffered damage to a disk, even by needling, may not yield any radiographic evidence of it for many months, and some do not develop symptoms sufficiently severe to cause them to seek surgical attention for five, ten, or more years, and at this time radiographs show definite evidence, such as diminution of the intervertebral disk space and splaying out of the approximated bony surfaces. The number of patients who show radiographic evidence of damage to disks is small compared with the number who show reactive changes in the borders of the vertebral bodies and articular facets. An

The above illustrations (greatly enlarged), show Pollen Grains which are among the main causes of Hay Fever.

When the POLLEN clouds rise HAY FEVER AND SUMMER COLDS

During the months of July and August, your hay fever patients will be seeking your advice for relief from the usual nasal congestion, sneezing and other discomforts of hay fever.

Prompt relief for such cases can be obtained by the use of 'Endrine,' which ensures comfortable breathing and has a bland, soothing effect on the inflamed nasal mucous membrane.

Now available in 2 varieties

TREATMENT OF ANÆMIA

with

COLLIRON

(colloidal iron hydroxide)

Colliron provides iron in a palatable and assimilable form for the treatment of iron deficiency anæmias and for supplementing dietary intake, particularly in invalids, expectant and nursing mothers.

Colliron is colloidal iron hydroxide with copper, cobalt and manganese. Each drachm contains the equivalent of 6 grains of metallic iron or 32 grains Ferri et Ammonii Citras.

Issued in Bottles of 4 oz., 8 oz., 40 oz. and 60 oz.

Colliron capsules containing iron, nicotinic acid and aneurine hydrochloride are also available.

Issued in Bottles of 30 and 250 capsules.

For further particulars apply to:

STILBOESTROL and related SYNTHETIC OESTROGENS

Every medical practitioner should send for a copy of "Stilboestrol and Related Synthetic Oestrogens"—a 32-page manual compiled by the scientific staff of Clinical Products Ltd.

This manual is designed to give quick, easy access to available data on these important substances, and covers the significant works of leading investigators in the field of Stilboestrol research.

Menopax preparations—both the tablets and the anti-pruritic cream—are in constant and ever-increasing production to meet demand. Free medical samples and a copy of this book (to satisfy Paper Regulations please send one penny stamp) will be gladly forwarded on application to:—

Clinical Products Ltd.,
Richmond, Surrey.

"... a complete
guide to the
applications of
synthetic oestrogens
in clinical
practice."

Dakin and West's Erythropoietic Fraction of Liver

Although Anahæmin B.D.H. is primarily indicated for the treatment of pernicious anæmia, clinical evidence indicates that it also exerts a marked tonic effect on tired and debilitated patients. Its effect is remarkably rapid, and it may be assumed that it is attributable to a stimulation of tissue oxygenation.

Anahæmin B.D.H. may be employed, therefore, for the relief of subclinical and minor degrees of weakness, debility and undue 'fatiguability' as well as post-infective debility and prolonged convalescence. A dose of 2 c.c. is suggested, followed by a further dose of 1 c.c. or 2 c.c. five to seven days later if necessary. Further information will be supplied on request.

analysis of the radiographic indications of many other causes for these symptoms has been recorded (Brailsford, *Brit. J. Radiol.*, October, 1944, p. 308).

One has witnessed a considerable display of fashion in the alleged cause for low back pain. Disk lesions are now at the crest of the wave. Jefferson (*Med. Ann.*, 1944, p. 171) has stated, "There are few to-day who deny that the most common cause of sciatica is rupture of the intervertebral disk," but the adoption of operative measures for its relief one hoped was on the wane. I cannot help but think that many were undertaken without adequate study of the normal and its infinite variations, and I appreciate the candour of Holmes and Sworn who state, "Two cases had what we thought was some thickening of the ligamentum flavum, but this may have been within normal limits." Such expressions direct us to their more helpful statement: "There is no doubt that most cases of 'sciatica' will clear up spontaneously, or can be cured or relieved by relatively simple measures without resort to surgery."—I am, etc.,

Birmingham.

JAMES F. BRAILSFORD.

Blindness in Nigeria

SIR,—Dr. J. Graham Scott in his letter on this subject (June 22, p. 964) confuses the issue, for he does not seem to appreciate that the flora and fauna, the dietary habits of the natives, and the prevalent diseases vary with the climatic conditions. Nigeria is a very large territory; the south is in the tropical rain forest belt, while the north, where the census in question was held, is at the edge of the Sahara. His statements are more nearly correct in the south and central zones, but in Bornu, in the extreme north-east of the colony, his statements do not apply at all. In the original article I was careful to point out that the figures given related to this area only. They must not, in any circumstances be applied to any other area in the colony or in West Africa generally.

The following specific points are raised by Dr. Scott's letter.

(a) Ophthalmia neonatorum was common and was seen frequently in the out-patient department of the hospital and at the infant welfare clinic.

(b) The native of Bornu does not like red-palm oil. The oil palm is not indigenous in this area and any oil imported into the province has to be brought first by rail to the railhead and then almost 400 miles (650 km.) by road. This makes the price prohibitive for the general population, and it is only consumed by the relatively well-paid Government and commercial clerks, who are usually southerners and for whom the oil is a normal article of diet.

(c) One is taught that trachoma is an endemic and epidemic disease and that its spread is facilitated by insanitary conditions and poor nutrition. If it were present in these large native towns it should spread like wildfire. In fact, however, very few cases are reported annually from the hospitals in the most northerly provinces in Nigeria. The diagnosis of the disease is not difficult even to one not specially trained in ophthalmology, and I can only suggest that it is not so prevalent as Dr. Scott would make out.

(d) Onchocerciasis is very common in some areas in Nigeria, particularly in the southern provinces, and the statement by Dr. Scott that 50% of the population is infected may be correct in these areas. The climate of Bornu, however, is unfavourable for the vector, *Simulium damnosum*, and where the vector cannot breed easily the disease cannot exist to any large extent.

Leeds

FRANCIS E. STOCK.

"Tropical" Eosinophilia

SIR,—You state (June 8, p. 884) that Loeffler's syndrome differs from the tropical eosinophilia "in that it occurs in dry and temperate climates." This is not correct. Loeffler's syndrome was described by myself simultaneously with Loeffler in 1932 in Shanghai, which has an extremely humid, tropical climate during the summer months.

In my first publication I named the so-called Loeffler's syndrome "allergic spring oedema of the lungs." I then suspected that a pollen may be the responsible allergen. This supposition was based on the fact that certain people developed signs of lung oedema every spring, approximately at the same time. My first observation was made on myself. I further called attention to the fact that Loeffler's cases also showed a seasonal incidence with a distinct summer peak. This was since admitted by Loeffler and confirmed by others. I also denied any connexion between my syndrome and tuberculosis, then

suspected by Loeffler. I had no opportunity to follow up my observations in the Tropics, but it might be of significance, and in support of the pollen theory, that since I came to Britain in 1936 I have had no attack of spring oedema though I was subject to it in Shanghai every May or June for several years.

Since my publication two other observations of similar nature were made, one in China, the other in Japan. Case 4 of M. H. Chien and T. P. Wu most probably belongs to this group. They mention also that during spring of each year they see patients suffering from "cold" with cough and malaise and sometimes slight fever. They are generally treated as out-patients. Some are admitted to hospital for some surgical condition, and x-ray examination of their lungs shows patches of soft infiltrations which are usually absorbed completely in a short time. The sputum, when present, is scanty and contains no tubercle bacilli. Chien and Wu could not know then of the existence of my syndrome, which was published in the same issue of the *Chinese Medical Journal* as their paper. The case observed in Japan was published by I. Hatakeyama, who called it "temporary infiltration of the lung caused by high-grade tuberculous allergy." The assumption of tuberculosis was based on a positive tuberculin test. This, in a boy of 15 years, especially in Japan, is very unconvincing. The patient showed slight clinical symptoms but a very extensive and dense shadow of the upper lobe which disappeared in two weeks. The patient had eosinophilia. This, in my opinion, is a typical case of my syndrome.

I have no experience with the tropical eosinophilia of Weingarten, but from his description it appears to me that his disease is of a more serious nature, inasmuch as it causes the patient much more inconvenience and lasts longer, while my syndrome is often detected only by chance and usually does not cause any serious symptoms. The x-ray findings of the two syndromes also differ. It is possible, however, that different allergens cause different reactions in the lung, as shown in bagassosis, in which the allergen is melasse.—I am, etc.,

Dewsbury.

What is Clinical Pathology?

SIR,—In so far as any distinction can be drawn between "clinical pathology" and other aspects of pathology, it would presumably be the distinction between laboratory investigations applied to diagnosis and control of treatment in individual patients and investigations directed to the elucidation of the fundamental problems of the science. The distinction is certainly not between the simpler and the more specialized techniques, and I entirely agree with Dr. A. C. Lendrum's emphasis (June 1, p. 848) on this point. Every pathologist, whatever his special branch, is acting as a clinical pathologist when he is concerned with individual diagnosis. It would be most undesirable if the distinction between work required for the immediate service of patients and work on fundamental questions should be made the basis of a separation of specialties, either from the administrative standpoint or in defining the scope of journals.

Much work on human material, done in laboratories attached to hospitals, is concerned primarily with fundamental scientific problems, and such work takes its place, together with animal experimentation, in the progress of the science of pathology. On the other hand, every new advance in diagnostic methods rests upon the medical sciences. In my own field of chemical pathology the development of new diagnostic methods involves chemistry, physiology, pathology, and clinical medicine. Yet I think there is a place for a new journal devoted to those investigations of disease in man in which both the clinical field and the medical sciences are involved. Publications of work on human material, whether directed to fundamental problems or to diagnostic requirements, must often include clinical case histories or summaries adequate to give the medical reader an understanding of the nature of the material, and may also include technical and scientific matter too specialized for the

general medical journals. Such papers are apt to be more difficult to place than those falling clearly within either the "clinical" or the "scientific" field.

Whether the new journal has the title "Quarterly Journal of Clinical Pathology" or some other title, it is to be hoped that its scope will not be conceived as covering only the narrowly diagnostic aspect, but will be wide enough to include other work on human material, and especially investigations of disease in the living patient.—I am, etc.,

Newcastle-upon-Tyne.

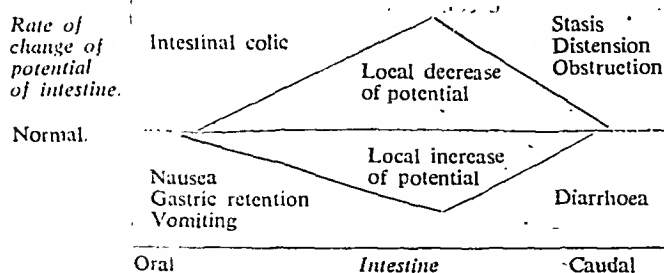

FREDA K. HERBERT.

Neurogenic Ileus

SIR,—I found Mr. J. T. Chesterman's paper on neurogenic ileus (June 1, p. 830) interesting. It shows a great amount of thought and work and an understanding of a theory. The theory is badly expressed because an unsuitable word is used, and this becomes patently obvious on careful examination of the diagrams which are intended to convey the essentials of the theory. I am not in a position to discuss the theory, but it is deplorable that it should be expressed in an unsuitable form which is certain to hamper its development.

"A" of Fig. 1 graphically defines flattened and steepened gradients. Analysis of "B" on this definition shows a local focus preceded by a flattened gradient and followed by a steepened gradient. This is called "local focus causing steepening of gradients." Why? It could equally well be called "local focus causing flattening of gradients." Similarly, "C" is called "local focus causing flattening of gradients" but could equally well be called "local focus causing steepening of gradients." The diagrams do not represent "intestinal gradients" but they do try to represent "rate of change of intestinal gradient," and these two are as different as a curve is from a straight line; as different as $y=x^2$ is from $\frac{dy}{dx}=2x$.

It is apparent that the unsuitable word is gradient. A gradient is a thing of precision, a straight line at a precise angle to a base line. A change from one gradient to another gradient happens precisely at a point and you cannot examine the intestine and pin-point the place where the "gradient changes." By differential calculus one can visualize a gradual change as a multiplicity of minute straight line changes of gradient spread over a length of intestine—but the word gradient by itself in no way implies this gradual change. May I suggest that the word "gradient" be discarded and the word "potential" used instead. The essentials of the theory would then be written as follows: A focus causing local increase of potential produces a decreased rate of change of potential on the oral side of the focus with decreased activity and an increased rate of change of potential on the caudal side with increased activity. Similarly, a local decrease of potential is preceded by an increased rate of change of potential and followed by a decreased rate of change of potential. This is easily and precisely expressed graphically.

The essential simplicity of this nomenclature, which specifies the nature of the focus and then describes the changes each side of the focus, should be compared with the nomenclature of the focus by reference to the change on one side of the focus without specifying which side. It is not possible in the space of a letter to go into the full application of this change of nomenclature, but surely I have shown how the use of the word "potential" instead of the word "gradient" leads to a logical expression of the present theory. Looking to the future, I suggest that potential will be found to be the right word when research is concerned with the minutiae of electricity in living matter.—I am, etc.,

Birkenhead.

ALEX. M. FRASER.

Penicillin for Diphtheria Carriers

SIR,—I started to try local treatment of diphtheria throat carriers by means of applying every two hours a solution containing 2,000 units of penicillin per ml. A night interval of 8 hours is observed. I have so far treated three cases, only; the results are entirely encouraging, as no more diphtheria bacilli could be obtained in culture from repeated smears after 13 applications, totalling 67,000 units of penicillin. I would not consider it wise to wait for more cases before giving publicity to this possibility of treatment, as it is essential to induce other workers to make similar trials at the earliest opportunity. Should more attempts prove the efficaciousness of this method, there is no need to stress its far-reaching importance in the control of diphtheria.—I am, etc.,

General Hospital, Cieszyn, Poland.

W. BINCER.

Inhalation Apparatus for Penicillin

SIR,—We note the report in your issue dated June 15 of the meeting of the Royal Society of Medicine, when the uses of penicillin were reviewed and questions were asked about the availability of inhalation apparatus. It seems appropriate to offer an explanation why the special inhalation and other apparatus developed by this company has not been made generally available.

When we first produced aerosols by what is now generally known as the "phantomiser" system the immediate practical applications were for the control of different kinds of pests, and subsequently for air disinfection generally. Throughout the war our energies were almost wholly devoted to the production of apparatus for these purposes, and, whilst we were fully aware of the potentialities of aerosols in medical practice, the development of production of inhalation and other apparatus for this purpose was severely restricted. The possibility of being able to replace the repeated injection of penicillin, and other medicaments normally requiring parenteral administration, by a simple efficient inhalation technique is so novel that even now we are reluctant to place apparatus on free sale until further convincing trials have been completed. The findings of these trials will be published in due course.

For the production of wet sprays of small particle size there are several excellent machines available commercially, but it is important to remember that a true aerosol can be produced only by apparatus specially designed for the purpose, such as the "phantomiser" and "aerolyser" manufactured by this company.—I am, etc.,

London, W.1.

A. K. BEDWELL,
Director, Aerosols, Ltd.

Health Service Bill

SIR,—If once the people of Britain realize that the medical profession are not fighting for themselves alone but for the freedom of this country as a whole, they will surely rally to their aid. It would be well, then, to appreciate that it is not health *per se* that the battle really rages around, but freedom or bondage.

At present the health of the people actually depends far more on good housing, good feeding, good clothing, good education, and freedom from the incessant irritations interminably imposed by increasing controls and restrictions, rules, and regulations, which predispose to, or actually cause, ill-health, than upon a chaotic revolution in the medical world for the sake of vindicating Socialist doctrinaire theories. Until these primary matters are rectified there is little use in the politicians trying to saddle the medical profession with responsibility for the state of the nation's health, be it good, bad, or indifferent.

Power-seeking politicians are well aware that complete control of the people, which is essential to their policy, can only be secured by first completely controlling the medical profession. This is to be achieved by tempting or bullying them into becoming State-paid, State-instructed medical officers, dependent or largely dependent for their living on being efficient Government tools, subject to direction and instruction from the "minister-dictator of health," who does not negotiate but "rules by regulation." Such rules and orders are nothing less than dictator-made laws; beyond the real control or scrutiny of Parliament itself. Do the people of Britain consciously stand for this chicanery in the name of health? The Bill in its present

form is a Socialist measure for which no true mandate from the country has ever been given to this, or indeed to any, previous Government, whatever is stated to the contrary. A Socialist majority can, and no doubt will, ram the Bill through. Thereafter the only course open to the profession in the interest of the whole community is to refuse to sign any operative contract with the Government, and thereby retain their liberty. This proved successful in New Zealand under similar coercive circumstances.

Little more than a year ago we fought for our very existence against a country which had yielded up its freedom to political power-seekers. With this terrible example before our eyes we we, like they, going to walk into this cunningly devised trap of "National Socialism," a gilded cage of bondage from which there can be no return to freedom? Belsens and Buchenwalds are the logical outcome of dictator-made laws when resistance or protests run counter to the whims or fancies of "dictator-ministers." Do not delude yourselves with the thought that "it could not happen here"; steadily it is happening. Power breeds the lust for power, and any discerning person can observe its erosion on the freedom of this country day by day.

People and doctors alike favour improved health—who does not?—but not as devised in this Bill, which aims at improved political power for politicians, not improved health for the people. It would make the community disease-conscious, would quadruple the work of the already overworked hospitals and doctors by overloading them with trivialities which undoubtedly would be the outcome of so-called free treatment. To control this increased traffic in sickness and drain on the Treasury it would become necessary to issue regulations to medical officers to issue certificates as instructed by the State, not in the interest of the patient, but of the State. The medical officer, being a State servant in greater or lesser degree, without alternative source of employment and therefore owing allegiance to the State for his bread-and-butter, would of necessity have to consider the State's interest first, last, and all the time, to the very great detriment of the patient.

There are insufficient doctors or hospital beds in the whole of the United Kingdom to cope with the increase in sickness incidence which this Act would bring about. The disgruntled, disillusioned, dejected, despondent, and dreary State doctors will not easily radiate health and happiness to the pathetic patients in like plight to themselves; no, not even if directed to do so by the Minister of Health, strange as that may seem.—I am, etc.,

St. Annes.

G. H. URQUHART.

SIR,—Less than two months ago a Special Representative Meeting passed with great unanimity a number of resolutions. They were, for example, firmly of the opinion that goodwill in practice should be retained, that there should be no direction, that payment should be exclusively by capitation, and that there should be no discrimination against doctors who remained outside the public service. Not a ripple has all this caused on the calm waters of the Ministry. The profession's representatives have been as completely ignored as if they were some babbling collection of village busybodies.

While we are grateful to Mr. Willink, Mr. Reid, Mr. Strauss, Mr. Law, and others for doing their best to put the profession's case in Standing Committee C, they, too, have been completely flouted by an automatic majority echoing the constant urge of the Minister: "Let us not waste time on windy argument. This Bill must go through!" Needless to say, the Minister has displayed great knowledge of professional affairs. He has said that when a practice is sold it is only the panel portion which has any monetary value, the private part being valueless. He has said that it is undesirable for sons to follow their fathers in practice, as this may lead to "inbreeding." He sticks to his desire to gaoil any doctor who makes a profit on selling his house, and he is denying the use of the hospitals to doctors who remain outside his scheme. In short, there is no doubt that this Bill will become an Act unmodified in the slightest way by the unanimous resolutions of the British Medical Association. What then? Time drags on. It may yet be eighteen months before doctors are to say whether or not they will serve under Mr. Bevan or under Hippocrates. Meanwhile, fatalism sits like a load on our shoulders, and it has been unkindly said that the warriors of yesterday are the mathematicians of to-day, working out what their compensation is likely

to be—unmindful of the hard fact that that compensation will be rather less negotiable than a post-war credit certificate.

The real difficulty is that it takes a lot of moral courage for a doctor, not too well off, with a wife and family to support, to stick out against the coffers of the Treasury, to put his professional soul higher than the plain risks of bankruptcy. Dr. X, of Devonshire, may well say to himself: "I would stand out, but I should hate to be the only one doing so. And how am I to know what Dr. Y, of Lancashire, will do?" To ask the doctors of the country to keep their passions hot for a year or more, and then to remember all that has gone by and to turn down this scheme, as it should be turned down, is asking for something that may not happen. There are still doctors one meets who will say with great pride: "I was one of those who stood out in 1911." But there are not many of them. Who will be able to say, in thirty years' time, "I was one of those who stood out in 1947"?

But there is a way out. This scheme, like peace, is indivisible. Passive resistance stoutly sustained over a few wide areas would make it unworkable. There are areas more convinced of the importance of freedom than are other areas. Let them but stick to their guns and they will win. More, they will encourage the others to follow their lead. Yorkshire, Surrey, Kent, the Metropolitan Counties—your power is in your own hands. It does not depend on the waverers elsewhere. We are a great profession. We have a right to be heard, to be consulted in these matters. Let us stand on our right.—I am, etc.,

Ashted, Surrey.

W. EDWARDS.

SIR,—The new National Health Service Bill when passed into law will do much to co-ordinate and bring up to date our health services. There is, however, likely to be a time lag before the new service can do itself full justice, if only on account of the shortage of suitable buildings for health centres and hospitals. The health services have been chosen as the first branch of national economy to be nationalized by the Labour Government, and with a policy of limited nationalization now being followed it is inevitable that the development of the health service will in the first place be handicapped by the fact that industry in general remains in private hands. Thus it is apparent that if the building programme called for to make the service fully efficient is put out to private contractors huge profits will pass into their hands, thus greatly increasing the cost of the service and reducing the speed of construction.

I would suggest that Mr. Bevan would do well in dealing with this obstacle to progress to consider the example set by Edmonton and other progressive local authorities which have a fine record of building by direct labour. Is there any reason why the new hospitals which we need so badly should not be built by direct labour employed by the new regional hospital boards, and the health centres by the building departments of the major local authorities? The new buildings which are so urgently required could then be erected more cheaply, quickly, and efficiently.—I am, etc.,

St. Mary Cray, Kent.

BRIAN H. KIRMAN.

SIR,—The profession should be grateful to Dr. W. Edwards for his letter (June 15, p. 926) emphasizing the significance of Mr. Bevan's remarks in Committee. All our efforts will have been in vain unless we can secure two essentials: (1) The terms and conditions in any National Health Service must be acceptable to (and not accepted under economic stress by) the majority of the profession. (2) Those of us who wish to remain outside the service must not be penalized. Surely, the public has never expressed its desire for a State monopoly of medicine?—I am, etc.,

Dorking.

CYRIL E. BEARE.

The Hypochondriac's Treatment

SIR,—In the press Dr. Edith Summerskill is reported to have said that "in future no doctor need prostitute his science by pandering to hypochondriacs. The malingering will find short shrift in medical health centres. The doctor of the future will be judged not by the size of his bank balance, his house, and car, but by his capability to prevent and cure diseases." Does Dr. Summerskill really believe that her colleagues are

so deficient and the general public so credulous as to measure a doctor's capability by these criteria? Surely the hypochondriac is in need of careful and sympathetic treatment, and even the malingerer requires not short shrift but a most careful investigation, first as to the accuracy of the opinion, and secondly of the economic factors leading to such conduct.

If this is to be the aggressive spirit animating the new health service let the profession and the general public take warning before it is too late.—I am, etc.,

Bournemouth.

E. D. GRANGER.

Obituary

ERNST FREUND, M.D.

Prof. Ernst Freund, born in Vienna in 1863, died in London on June 2, 1946. He studied medicine at the University of Vienna, was a brilliant student, and obtained his M.D. at the age of little over 22. In the mid-nineties of the last century he became director of the biochemical department of the "Rudolf-Spital," and remained in that position for almost forty years. When later he was made professor of pathological chemistry in the university, he worked in his old laboratory until he reached the retiring age. At that juncture, when Freund was in danger of being left without any opportunity to continue his work, Mr. F. F. A. Pearson put into being the "Pearson Cancer Research Foundation" to enable him to carry on his research. When Austria was overrun by the Nazis Mr. Pearson transferred the Foundation to London, where Freund worked to his last day.

The early years of Freund's career (writes F. S.) coincided with a glorious period of continental science. At that time Freund did some outstanding work on the problem of blood clotting. One of the results of his experiments was the use of sodium citrate as an anticoagulant. At a meeting of the "Gesellschaft der Aerzte" in Vienna he suggested the use of it for blood transfusion (1891). Freund's researches covered a wide field. His institute was a part of one of the best Viennese hospitals at its best time. At the beginning of this century he worked in close collaboration with men like Paltauf, Pick, Sternberg, Kraus, Bamberger, and Obermeyer. Many new methods of biochemical analysis were devised by Freund and his co-workers. Special care was given to urine analysis, and Freund was able to demonstrate the presence of enzymes or enzyme-like substances which were believed to be specific for various diseases. Another line of research for many years successfully pursued by Freund was concerned with the physiology and pathology of digestion. He tried not only to explore and to determine the products of digestion in normal and pathological conditions, but he also aimed at elucidating the mechanism of the absorption of these metabolites through the intestinal wall. These studies were followed by investigation on the mechanism of protein synthesis within the living body.

From his early days Freund devoted much zeal and time to the study of tuberculosis and published several papers dealing with biochemical aspects of this disease. Also rheumatism fell within the scope of his work. His main interest, however, was the problem of malignant growth. Freund came to conclusions which are well in keeping with the results Warburg obtained more than 40 years later. With his collaborator, G. Kaminer, he described the cytolytic reaction which he modified and revised in many respects in later years. The technique of this test was much too complicated to become a routine method. It is, however, fair to say that those few who have mastered the technique agreed that the results were better than those achieved with any other cancer reaction. Freund's belief in biochemical changes in cells as a predisposing factor of malignancy growth led him to therapeutic assays. He tried to influence the pace of growth by dietetic means; long before the importance of *B. coli* for the vitamin contents of the body was known he stressed the importance of maintaining a normal bacterial flora in the gut. He also suggested several therapeutic methods aiming at the restoration of the normal intestinal flora.

More than 200 papers are the scientific inheritance that Freund has left to posterity. With an unquenchable spirit he devoted his life to science and to the fight against disease.

The death occurred at Bath on June 12 of Dr. HERBERT CASTLEMAN JEFFREYS, who had had a very varied career in many different parts of the globe. His father, Herbert Jeffreys, was one of the early settlers in Victoria; but H. C. Jeffreys, his only son, was actually born in 1874 near Taunton, though his father returned with him to Australia while he was a boy. He was educated at Sydney Grammar School, then at Melbourne

University, and then at New College, Oxford. After taking his arts degree with honours he studied medicine at St. George's Hospital in London, whence he qualified as M.R.C.S., L.R.C.P. in 1898. After holding the usual resident appointments at his own hospital, he next served in the South African war as civil surgeon with a yeomanry field hospital unit. After that he entered the Colonial Medical Service and spent a few years in British Honduras. Returning to Australia, he found it uncongenial and rejoined the Colonial Service, this time in Nigeria, when he finally retired in 1925. He had taken the D.T.M. at Liverpool in 1906 and the D.P.H. at Cambridge in 1912. In Nigeria he was for a time inspector of a leper colony, and after his retirement he indulged freely in his hobby of foreign travel. A further African experience fell to his lot as medical officer to the Tanganyika Concessions Expedition to Angola, in Portuguese West Africa. An earnest, kindly, hardworking, and yet modest man, Jeffreys had many friends and few enemies. He was unmarried.

The death of Squadron-Leader ROBERT WILLIAM STANLEY MARSHALL has now been officially announced. The only son of Dr. and Mrs. Robert Marshall of 9, College Gardens, Belfast, he was born on July 12, 1916, and was educated at Methodist College and Queen's University, Belfast, graduating M.B., B.Ch., B.A.O. with honours in June, 1940. He was then appointed house-surgeon and physician at the Royal Victoria Hospital, Belfast, and joined the R.A.F.V.R. early in 1941. He married, in 1941, Hilary, elder daughter of Prof. and Mrs. P. T. Crymble. He served in Persia, Iraq, and India for three years before being appointed S.M.O. to No. 909 Wing, R.A.F., Burma, where he was killed on June 3, 1945, while on flying duties. J. B. Y. writes: His untimely death at the age of 28 removes from our midst one of the most promising of the younger members of the Belfast Medical School. To have known him as a boy at school, as a student at the University, as a houseman in the Royal Victoria Hospital, and in a more intimate sense in his own home, is to appreciate the grievous loss sustained by his family and many friends. Robert Marshall was characterized by his great natural charm and cheerfulness, by his thoughtfulness and loyalty. A cultured conversationalist with a broad outlook on life, his ready wit and love of humanity marked him as outstanding among his peers and was an indication of his maturer manhood. A brilliant scholar and undergraduate he gained many distinctions. He was a fine golfer and swimmer, a keen motorist and an ardent photographer. His work as a resident student and houseman in the wards of the hospital testified to his thoughtfulness and kindness to those in suffering and distress and to his knowledge of essentials and thoroughness in the practice of medicine.

Dr. GEORG KOSAK, who died at the early age of 38 on June 16 at his home in Winchmore Hill, London, was an M.D. of Munich and came over here as a refugee from Nazi oppression. After further studies he became L.R.C.P. & S. Ed. and L.R.F.P.S. Glas. A colleague writes: He soon took to the ways of life of this country which he grew to love very much, and when he eventually set up in practice he became a very successful doctor whose patients sought his professional and friendly advice alike. He was of a quiet and amiable disposition whose depth of feeling showed itself by some casual remark, and he had an unfailing sense of humour.

The following tribute to Mr. W. McADAM ECCLES comes from Mr. A. P. Bertwistle. A man's life is divided into three well-defined phases: The first, of education; the middle, of his life's work; and the third, of his retirement. This last only too often means lone rounds of golf, visits to deserted clubs, half-hearted efforts at gardening, etc., all leading to a premature decease. On the other hand it may mean a change in work; this was the case with Mr. Eccles. I first knew him at the end of the middle phase. One's first impression of him was of an aloof, prickly man, but this rapidly disappeared as one discovered his kindness. He was religious and a teetotaler, neither of which was an asset in popularity among medical students. For his teetotalism he had excellent reasons; he took a keen interest in drink addicts. He was a past-master with trusses. He had sound business instincts—his opinion on a financial question was always of the greatest help. He was a perfect correspondent, prompt and to the point. When the last war broke out he threw himself wholeheartedly into A.R.P. first-aid work. Towards the end of his life he took up the question of medical films with a vigour rarely found in a man of his years. He originated a scheme for obtaining the best out of them. He produced a "short" showing how blitzed casualties were dealt with; when it was shown at the local cinema so realistic was it that 14 people fainted, and the sheepish looks on those who had succumbed, when they saw how it had been faked, was a study. As a diagnostician he had few equals; I, for one, will ever be grateful for his discovery of a dental focus of infection.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on June 15 the following degrees were conferred:

D.M.—R. D. Newton.
B.M., B.Ch.—T. J. Thompson (in absence).

UNIVERSITY OF CAMBRIDGE

At a Congregation in the Senate House on June 24 the degree of Doctor of Science, *honoris causa*, was conferred by the Vice-Chancellor on five delegates to the Royal Society Empire Scientific conference during its visit to Cambridge. The medical recipients of the honorary degree were Prof. C. H. Best, M.D., F.R.S., head of the Department of Physiology, University of Toronto, and director of the Banting-Best Department of Medical Research; and Dr. F. M. Burnet, F.R.S., director of the Walter and Eliza Hall Institute for Medical Research, Melbourne. Introducing Prof. Best, the Public Orator said that he had won an honoured name in the realms of medicine and physiology and was joint leader of an institution which had made notable contributions to the relief of human suffering. Of Dr. Burnet he said that he excelled particularly in the field of bacteriology; his book *Biological Aspects of Infectious Disease* was famous and fully entitled him to wear the Cambridge scarlet.

The Marmaduke Shield Scholarship for 1946 is awarded to R. P. Holmes of Trinity College.

The following candidates have been approved at the examinations indicated:

FINAL M.B.—Part I (*Surgery, Midwifery, and Gynaecology*). A. Ackroyd, A. P. Baker, E. A. D. Boyd, G. A. Bracewell, G. T. F. Braddock, D. C. Bradford, J. H. S. Buchanan, A. O. Chase, L. W. Clarke, J. Crossley, D. E. Cullington, A. B. Douglas, W. M. Edgar, A. S. Fairbairn, G. R. Freedman, E. C. Glover, J. L. Harris, C. F. Hingston, E. M. James, C. S. Kirkham, J. G. Latimer, R. G. Law, D. M. N. Longridge, I. D. Mackichan, E. D. Marsh, D. G. Miller, D. V. Milward, J. L. Moffatt, D. R. Morgan, A. G. Norman, D. O'Brien, J. M. Palmer, E. E. Philipp, G. Raperport, P. Rhodes, D. H. Richards, D. W. T. Roberts, K. J. Roberts, P. W. Rowsell, B. E. Shairp, M. F. Smith, J. E. H. Stretton, M. K. Tower, H. Walstead, K. L. Williams, R. D. Williams, R. H. L. Volfsohn, G. M. Woodward, P. M. Yap, R. E. V. B. Young. *Women*: Mrs. E. W. Higgins, G. F. Jacob, G. A. Meigh, B. E. S. Richards, D. M. Robinson, P. M. Stanwell.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following lectures will be delivered at the College (Lincoln's Inn Fields, W.C.) at 5 p.m. each day: July 9, Prof. John Beattie: Physiology of Convalescence; July 10, Walker Prize Lecture by Dr. Peyton Rous: The Antecedents of Cancer; July 11 and 18, Charles Tomes Lectures by Sir Frank Colyer: Dental Disease in Animals, and Positional Variations in Animals; July 25 and Aug. 1, Hunterian Lectures by Prof. W. D. Coltart: Injuries of the Astragalus, and by Prof. A. L. d'Abreu: War Surgery of the Chest.

Dr. Peyton Rous, of the Rockefeller Institute, New York, will give a lecture on "The Antecedents of Cancer," on Wednesday, July 10, at 5 p.m., at the College. Dr. Rous was awarded the Walker Prize for 1936-40 for his discovery and systematic investigation of filtrable tumours, and is now paying a visit to this country to lecture and visit centres of cancer research.

A course of 68 lectures on anatomy, applied physiology, and pathology will begin at the College (Lincoln's Inn Fields, W.C.) on Sept. 2 and will continue until Oct. 18. There will be two lectures daily from Monday to Friday each week at 3.45 p.m. and 5 p.m. The fee for the whole course is £15 15s.; it will not be possible to take one or two subjects only. Applications accompanied by a cheque should be sent to the secretary of the College. Fellows and Members will be admitted without charge, but must apply for a card of admission.

At a meeting of the Council of the College held on June 13, with Sir Alfred Webb-Johnson, Bt., President, in the chair, Sir William H. Collins handed to the President a cheque for £100,000 which he promised in February last as a further gift for the scientific departments of the college, in encouragement of the project for an Academic Medical Centre in Lincoln's Inn Fields.

There was presented to Prof. E. C. Dodds, of the Middlesex Hospital, a cheque for £1,000, being a prize given to him by Mr. Charles Mayer, of New York, in recognition of his work in discovering and studying stilboestrol, and as a contribution for his further researches in the field of synthetic hormones.

Diplomas

Diplomas of Fellowship were granted to the following candidates:

L. O'N. Knox, W. Bullock, S. H. C. Clarke, G. C. Tresidder, J. F. H. Butman, W. M. H. Shaw, C. J. Evans, R. S. Murlay, J. H. Penrose, B. J. Harries, H. F. Lunn, J. S. H. Wade, P. F. Milling, R. G. Barclay, Muriel Crouch, J. W. P. Gummer, G. K. Tutton, W. J. Atkinson, Carolina M. van Dorp, F. R. Wilde, A. Elton, P. R. N. Kerr, M. E. Minchin, T. L. T. Lewis, G. D. Adhia, S. G. Aulken, C. E. Baker, E. V. Farling, A. K. Basu, J. K. Bors, W. S. Charlton, W. P. Cleland, K. Coen, V. V. Da Silva, J. B. Devine, M. R. Ewing, G. J.

Fraenkel, H. K. M. A. Hassah, G. F. Homer, F. L. Hutter, A. M. Khan, M. M. Kinawy, R. J. B. McEwen, J. W. McNamara, G. B. Morris, R. Nigam, R. A. C. Owen, N. K. Parikh, A. P. R. Pinto, V. G. Renowden, D. G. Simpson, J. McN. Tainsh, D. F. Thomas.

A diploma of Membership was granted to T. L. T. Lewis.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following candidates:

R. E. Adam, A. F. Alsop, F. J. Aumonier, J. W. L. Bain, C. T. Barry, V. T. Baxter, P. H. Blackiston, J. A. Bolster, J. D. Bourke, A. K. Brown, C. H. Bulcock, J. H. Capon, P. S. Cheshire, K. S. Crawford, G. N. Deshmukh, S. Dobbin, T. M. Doran, G. A. Eason, B. Fairburn, J. N. Fell, Eileen M. R. Ghey, D. T. Gilchrist, Alexandra Goldblat, D. W. F. Gotla, H. W. C. Griffiths, Eileen M. L. Gunderson, J. Hutton, Margaret D. W. Hamilton, A. W. Hardie, J. B. Hargreaves, A. G. Hegarty, P. J. Helliwell, A. J. H. Hewer, E. Holden, Elizabeth A. Hout, D. D. C. Howat, E. G. Hudson, E. James, Flavia Z. L. B. James, Emily E. Johnson, D. S. Jones, Olive M. G. Jones, W. M. Jones, B. S. Kent, R. C. Lawrence, R. Lawrie, Janet E. Leng, J. M. Lockett, K. McCaul, Elizabeth McKenzie-Newton, D. Macpherson, F. W. Marshall, Sheila Millar-Danks, P. L. F. Mortimer, J. F. Perredes, Marie E. Potter, K. J. Powell, I. A. Schalit, M. Shaw, A. D. Sinclair, J. A. Smart, J. Sneddon, L. W. Spratt, G. S. Steele-Perkins, E. Stevenson-Wright, Margaret M. G. MacH. Sweeney, A. I. Ward, Kathleen M. Watson, O. M. Watt, R. J. Whiting, Dora M. Youne.

The following hospitals were recognized for the six-months resident surgical post required of candidates for the Final Fellowship Examinations:

Prince Bijay Singhji Memorial Hospital, Bikaner (three general house-surgeons); Central Middlesex Hospital (the third A.M.O. surgical and three additional surgical posts for as long as the Ministry of Health scheme for ex-Servicemen is in force); Clatterbridge General Hospital, Bebington (the resident surgical officer).

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At a meeting of the President and Fellows of the College, held on June 6, the following were admitted licentiates and members:

B. G. Alton, M. I. Drury, B. Moshal, H. J. Cronhelm, R. G. Cross, Sheila Sheehan, E. W. L. Thompson.

The Services

INDIAN MEDICAL SERVICE DINNER

After a lapse of seven years the annual dinner of the Indian Medical Service was again held in London at the Connaught Rooms on June 19, when 83 serving and retired officers met under the presidency of Lieut.-Gen. Sir Ernest Bradfield. The guests were Surgeon Vice-Admiral H. St. C. Colson, Medical Director-General R.N.; Air Marshal Andrew Grant, Director-General R.A.F.M.S.; Lieut.-Gen. Sir Alexander Hood, Director-General A.M.S.; Lord Moran, P.R.C.P.; Sir Alfred Webb-Johnson, P.R.C.S.; Mr. Eardley Holland, P.R.C.O.G.; and Mr. H. S. Souttar, President British Medical Association.

Work of the I.M.S. and I.A.M.C.

After the Royal toast Sir Ernest Bradfield proposed the toast of the Indian Medical Service and took the opportunity of outlining the work of the Service, and of the Indian Army Medical Corps which had been developed from it, during the war. In 1939 the I.M.S. was in a more flourishing state than it had been for some years. The military side with its military hospitals had attained a corporate spirit so long denied it in the individualism of the old regimental system. The civil side still offered opportunities for interesting and important work, though many of its responsibilities in the civil medical administration had been absorbed by an independent medical profession, for the growth of which the I.M.S. has been responsible. In September, 1939, the strength of the Service was 631 officers, of whom 265 were in civil employment. At the end of the war with Japan the Service, including the new Indian Army Medical Corps, had 7,625 officers, of whom 108, and 31 re-employed retired officers were in civil employ. Included in these figures were 206 women doctors, of whom 53 had been recruited in the U.K. The pre-war strength of the Indian Hospital Corps was 12,000; at the end of August, 1943, the strength in Indian officers and other ranks was 156,393. It is of interest to compare these figures with those of the 1914-18 war. At the commencement of that period the permanent strength of the I.M.S. was 770; it finished the war in 1918 with 793 permanent officers and 625 temporary officers—i.e., the recent effort was five times as great. During the war India mobilized over 1,000 field medical units, and provided 1,500 specialists. The total hospital bed strength reached 146,248, and the nursing services and amenities were really first class. Sir Ernest visited the Army Medical Training Centre at Poona last year, which is to carry on as an Indian Millbank. At one time there were 450 medical officers in training, and the results have been excellent. Indian doctors, who included a number of licentiates given commissions in the I.A.M.C., were not only taught the responsibilities of officers, they were given intensive field training and a special very comprehensive clinical course at Poona hospitals. Recruitment to the Indian forces remained on a voluntary basis throughout the war, and 23% of Indian graduates under 45 years of age and 12%

of the medical licentiates of the same age were recruited to the armed Forces. From May, 1942, recruitment of Europeans to the I.M.S. ceased, and the War Office undertook to provide from the R.A.M.C. British doctors required for duty with Indian troops. "The medical man-power situation in this country, however, became still more serious, and in 1942 I was a member of the Medical Personnel Mission appointed by the Secretary of State to visit India and to make recommendations. We are fortunate in having with us as guests to-night Mr. Souttar, the leader of that mission, and General Hood, Director-General of the R.A.M.C., who has proved himself to be one of the great administrators of this war, and I am glad of the opportunity of paying a tribute to a very happy association and to their great sympathy for the Indian Medical Services as well as for their wise counsel which solved this very difficult problem. It was clear that the medical authorities in India had been asked to build up a medical service to meet the requirements of an Army whose size and rate of expansion had never been envisaged by the General Staff. Although everything possible had been done it seemed that a breakdown could not be long delayed if existing conditions were permitted to continue. Great stress had been laid upon the shortage of doctors, but the real danger of the situation lay in the quality of the recruits provided for the Indian Hospital Corps and the scarcity of trained nurses. A system under which the officers belonged to one service, the I.M.S., the Viceroy's Commissioned officers and Warrant officers to another Department, the I.M.D., and the men to another Corps, the Indian Hospital Corps, was now obviously unworkable. The Mission, therefore, made proposals which were designed to provide one efficient and complete medical corps for all ranks of the Indian Army, and as a result came the I.A.M.C., a solution to India's medical problems which had been suggested before but never until now to provide an efficient medical corps including all ranks in one organization. There was no intention on the part of the Mission that terms and conditions of service of officers in the I.M.S. should be altered in any way, neither have they, but the Army Department has decided that the new corps should be an entirely military corps with no option of transfer to civil appointments."

After surveying the extent of the military effort of the Service and its high scientific record, General Bradfield concluded: "No one can foretell yet the future of the Indian Medical Service. Some of us, including practically all the senior serving officers, felt that our D-Day had arrived; but it is only logical that the disposal of all the Indian Services should be decided when a political settlement is reached as a result of the present negotiations. The creation of an Indian medical profession based on the ideals of British medicine has always been the aim of our Service, which founded the first medical colleges in India more than 150 years ago. The record and place of the I.M.S. in the building up of modern India is second to none of the great administrative services, and the I.M.S. will live in the I.A.M.C., in more than 45,000 registered doctors and the Civil Medical Services of India, who owe their existence in a very large measure to our Service."

The toast of "The Guests" was proposed by Major-General Sir John Megaw and replied to by Mr. H. S. Souttar who, as Chairman of the Central Medical War Committee, had been deputed to India in 1942 along with Sir Alexander Hood and Sir Ernest Bradfield to advise on the medical man-power situation in India in relation to the greatly expanding needs of the Forces. The result of the Mission had been the formation of an Indian Army Medical Corps in which all ranks were included, and he had had no hesitation after seeing the work of the Indian doctors in military hospitals in making the recommendation which led to this. He was specially appreciative of the work of the Indian licentiates who, on the recommendation made, were given commissions in the Corps. These men filled a serious gap, and their subsequent work fully justified the action taken. Mr. Souttar paid a tribute to the I.M.S., whose spirit had been diffused throughout the medical services in India. India would not forget the work of the Service, which would remain a great tradition.

Col. (Acting) R. D. Davy, M.C., R.A.M.C., has been appointed O.B.E. (Military Division) and Capt. P. M. Kirkwood, I.M.S., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services in the field.

Capt. J. H. Keesey, R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in the field.

The Efficiency Decoration has been conferred upon the following officers of the Territorial Army: Lieut.-Col. (Hon. Col.) W. A. Lister and W. H. D. Patterson, Lieut.-Col. J. C. Anderson, O.B.E., Major (Temp. Lieut.-Col.) T. F. Briggs, Majors (Hon. Lieut.-Cols.) W. R. Everett and J. J. Myles, Hon. Major H. F. Wattsford, Capt. (Hon. Major) R. E. Davie, M.C. (T.A.R.O.), and J. G. McDowell, and Capt. W. P. Blackstock, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died.—Major Samuel Barratt Browning, R.A.M.C.

Killed in air crash in Nigeria.—Capt. Reginald Thomas Moore and Evan McGregor Stirling, R.A.M.C.

Medical Notes in Parliament

HEALTH SERVICE BILL

On June 25 Mr. BEVAN moved that the Committee should meet in the morning and afternoon, so as to get the Bill through the House of Commons by the summer recess. There was agreement on many fundamental features of the Bill and an administration must start as early as possible to get the Bill into operation by 1948. Mr. Bevan's proposal was accepted.

— ASSISTANTSHIP WITH VIEW—OR WITHOUT

Resuming the discussion of Clause 35, the Committee agreed to a proposal by Mr. KEY to amend subsection 6 dealing with instances where a doctor performed services as an assistant to another doctor for payment substantially less than those services might reasonably be expected to be worth and afterwards succeeded to the practice. Mr. Key's amendment was to add after the words "expected to be worth" the further words "having regard to the circumstances at the time when the remuneration was fixed."

Mr. J. S. C. REID, discussing this provision whereby a low payment to an assistant should be deemed to have been a sale or part sale of the goodwill if the assistant subsequently succeeded, moved to insert "if" instead of "unless" in the proviso "unless it is shown that the said remuneration of the first practitioner was not fixed in contemplation of his succeeding to the said practice or any part thereof." Mr. Reid also proposed that the word "not" in the same proviso should be left out. In the proviso as it stood the Government proposed to put the onus of proof on the accused person in a difficult inquiry which might be entered upon after the passage of a number of years. A doctor could not possibly know if it was in the contemplation of the assistant that he would succeed to the practice.

Mr. BEVAN said Clause 35 had been very difficult to draft because the Ministry had sought to find a whole series of offences to protect the whole scheme. He would look at the Clause again to see if any of the fears expressed at the previous meeting of the Committee were justified and whether any cause for apprehension could be removed before the report stage. He thought he would be justified in resisting Mr. Reid's amendment. He asked how a prosecution was to know what had been in contemplation, and said it was reasonable to put the onus of proof on the accused person. The Government was trying to protect the assistant in these cases against being mulcted and having to accept an unreasonable reward at the beginning of his career. These prosecutions would arise very unusually. It might be that the assistant took a very small amount of money because he had no experience or because it was in his interest to become assistant to an eminent physician. Those would be justifications. In other words, the circumstances would have to be taken into account and the assistant would be asked: "What was in your mind when you took so small an amount of money?"

Mr. WILLINK accepted the assurances of the Minister that he would look into the Clause as a whole. He pointed out that there might be a running agreement for an assistant partly before and partly after the appointed day, whereby the assistant would succeed to the practice not under the partnership agreement but by selection by the medical practices committee. In those circumstances, nevertheless, there might be deemed to have been a sale of the goodwill. Mr. Reid withdrew his amendment. In doing so, he asked Mr. Bevan to re-examine what should be done with the assistant's agreements which were no longer appropriate.

CERTIFICATION BY MEDICAL PRACTICES COMMITTEE

Mr. BEVAN moved to leave out the final subsection (10) and to add:

"(10) Any medical practitioner or the personal representative of any medical practitioner may apply to the medical practices committee for their opinion as to whether a proposed transaction or series of transactions involves the sale of the goodwill or any part of the goodwill of a medical practice which it is unlawful to sell by virtue of this section, and the committee shall consider any such application and, if they are satisfied that the transaction or series of transactions does not involve the giving of valuable consideration in respect of the goodwill or any part of the goodwill of such a medical practice, they shall issue to the applicant a certificate to that effect, which shall be in the prescribed form and shall set out all material circumstances disclosed to the committee."

(11) Where any person is charged with an offence under this section in respect of any transaction or series of transactions it shall be a defence to the charge to prove that the transaction or series of transactions was certified by the medical practices committee under the last foregoing subsection, and any document purporting

to be such a certificate shall be admissible in evidence and shall be deemed to be such a certificate unless the contrary is proved: Provided that, if it appears to the court that the applicant for any such certificate failed to disclose to the committee all the material circumstances or made any misrepresentation with respect thereto, it may disregard the certificate and this subsection shall not apply thereto.

(12) A prosecution for an offence under this section shall only be instituted by or with the consent of the director of public prosecutions, and the medical practices committee shall at the request of the said director furnish him with a copy of any certificates issued by them under subsection (10) of this section and with copies of any documents produced to them in connexion with the application for that certificate."

Mr. REID moved to add to the words proposed by Mr. Bevan a further safeguard that if the medical practices committee did not within fourteen days of receipt of an application either issue a certificate or send a note to the applicant stating their reasons for refusing his application, they should be deemed to have issued a certificate. Mr. Bevan's amendment was good in principle but would only work properly if it could be worked speedily. He did not see how the medical practices committee could cope with this work without getting into arrears.

Mr. BEVAN said that almost all the work would be done by the executive council, and the medical practices committee would be in the background. The work in his proposed new subsections seemed to him the sort of thing the committee should do. If they imposed on the medical practices committee an obligation to give a reason why they refused to grant a certificate that would impose an obligation to give a direction or advice and would add to the work of the committee. Before long the medical profession would know what were reasonable conditions and what remuneration was paid to assistants immediately they started practice.

THE PRICE OF THE DOCTOR'S HOUSE

In reply to Mr. WILLINK, who asked: "And the price of the house?" Mr. BEVAN said it would be going too far to impose on the committee the obligation of saying what would be a reasonable price for a particular house, although they would take the price of the house into consideration in connexion with other things. There ought to be some way of conveying to the applicants to which part of the contract exception had been taken. He could not accept the imposition of the time limit.

Mr. REID asked what was to be done by a doctor's widow if she could not apply to the medical practices committee and ask whether she was free to take the top one of a number of offers made for her house. She must know beforehand or she would commit an offence as soon as the auctioneer's hammer fell. Mr. BEVAN said he was not concerned with the price the widow got for the sale. He was concerned with the influence on the succession. There was an offence where the price had an influence on the succession. Sir HAROLD WEBBE pointed out that unless a decision was given which enabled a successor to buy the house and enter into possession the local authority could take the house over within fourteen days of its becoming vacant.

Mr. REID withdrew his proposed amendment to Mr. Bevan's amendment and then moved to substitute a provision that the certificate issued by the medical practices committee should set out any facts known by the applicant to be relevant in place of Mr. Bevan's proposal that the certificate should set out all material circumstances disclosed to the committee. Mr. Reid said that as the amendment stood it would be possible to upset the certificate because of failure to disclose all the material circumstances. His object was to make sure that a man should only be prosecuted for having got a certificate when knowing that something was material he had deliberately withheld it.

Mr. BEVAN rejected the amendment and it was withdrawn. He thought it would be perfectly proper for the medical practices committee to take a newly disclosed fact into account for the purpose of invalidating a certificate. The Ministry might do something on those lines. When he said he would examine the language of the Clause the Committee must not assume he thought the Clause was wrongly drafted. He wished to avoid ambiguity. He accepted a contention advanced by Mr. Willink that unless the Ministry could make its intention more specific, existing partnerships might be seriously affected, and the partners would not know what to do. The words proposed by Mr. Bevan were then accepted and the Clause as amended was agreed to.

COMPENSATION FOR SCOTLAND

Clause 36 was next considered. In moving a drafting amendment Mr. KEY said three steps had to be taken. First there was the question of total compensation to be paid. That was put down at a figure of £66 million on the supposition that the number of doctors joining the service would be 17,900. If it

fell below that number then the total of £66 million would be reduced by 1/17,900 for every practitioner below the figure of 17,900. The second step was to decide the apportionment of the total figure between the services in England and Wales and in Scotland. That would be decided upon the relative losses of the people involved in those two sections. The third step was taking the portion that came to England and Wales and deciding upon its proper distribution. That distribution would be decided according to regulation which would be made after consultation with the profession. The amendment which he moved made it clear that not only the doctors in the service affected by the present Bill were included but also those who would give services under provisions applicable to Scotland when the legislation for Scotland had been agreed to.

Mr. BEVAN said the sum of £66 million was largely based on what practices were changing hands for before the war related to the number of doctors who would come into the public service. The Committee agreed to Mr. Key's amendment and also to an amendment by Mr. WILLINK to incorporate in the Bill the figure of 17,900 practitioners.

PAYMENT FORTHWITH

Mr. WILLINK moved to provide that compensation should be paid forthwith or as soon as practicable after the appointed day or the day on which the name of the doctor to whom it was payable was entered on any list of practitioners undertaking to provide general services, whichever of those days was the later. Mr. Willink said that for the majority of doctors, and their widows this was the bulk of their capital and might be the whole. His friends could not see why there should be a prohibition upon immediate payment.

Sir HENRY MORRIS-JONES said that Mr. Bevan's proposal was really a form of forced loan. Doctors had paid the money out and would have to continue paying interest at 4 or 4½%, as against the State interest of 2½%, until the loans were repaid. The Minister would gain the goodwill of the medical profession if he banded over the money.

Mr. BEVAN said that if he accepted the amendment the doctors would regard his act as evidence not of softening of the heart but of the brain. The money would be available to doctors when they normally received it—on death or retirement. Where there was great hardship the money would be paid out immediately. For £66 million to be handed over to the medical profession at once would have a most appalling effect. The money would be paid out at once where a young doctor had borrowed money at an unreasonable rate of interest.

Col. STODDART-SCOTT asked what Mr. Bevan proposed to do if the purchasing power of the £ fell greatly below what it was at present. Mr. BEVAN said other transactions did not make such an allowance, and transactions between doctors contained no such provision. The amendment was withdrawn.

On the motion that Clause 36 stand part of the Bill as amended Mr. SOMERVILLE HASTINGS asked for a ruling on the case of a practitioner who wished to withdraw from practice on health grounds and was paid his compensation. Supposing, that after a year's rest he recovered and wished to apply for a post in an under-doctored area. Would he be in order in doing so although he had received his compensation? Mr. BEVAN thought this would be in order but said he would like to consider the matter further. The Clause was ordered to stand part of the Bill.

No amendment was moved to Clause 37 concerning practitioners dying or retiring before the appointed day, but on the motion that the Clause stand part of the Bill, Mr. REID asked what would happen to the goodwill of a practice supposing the doctor died now. Did the Minister advise the representatives to sell that practice as soon as might be? Otherwise the representatives neither got value for the practice on a sale nor did they come in for part of the £66 million. Supposing the Act came into operation on Oct. 1 and someone died on Sept. 15. Was the practice to be sold or were the persons participating in the £66 million to be widened so as to include that case?

Dr. COMYNS said it was anticipated that the Bill would become an Act about October or November. He submitted that the application of Clause 37 to doctors who retired from practice or died during the period between the passing of the Act and the appointed day was too narrow. Practices of doctors who had died since the outbreak of the war had been carried on by locums, by assistants, or under the protection of practices scheme. The Minister should see if it was possible to embrace that category. Mr. BEVAN said he had it in mind to insert on the report stage a date which would cover the points raised.

Dr. STROSS said unless the date was retrospective gross injustice would be done to widows or doctors who had died recently. Since the printing of the Bill there had been difficulty in disposing of practices.

Clause 37 was ordered to stand part of the Bill, as were Clause 38 (arrangements for pharmaceutical services) and Clause 39 (persons authorized to provide pharmaceutical services). Answering Sir H. MORRIS-JONES on the last Clause Mr. BEVAN said arrangements would be made in rural areas for doctors to provide medicines.

After some discussion the Committee agreed to Clause 40 (arrangements for general dental services). Mr. BEVAN gave an assurance that it would be possible for dentists to appear in the lists of more than one executive council. The Committee then adjourned.

SUPPLEMENTARY OPHTHALMIC SERVICES

On June 26 the Committee examined Clause 41. Section 1 of this Clause says it shall be the duty of every executive council to make arrangements with medical practitioners and opticians having the prescribed qualifications for securing the testing of sight by them. Mr. LINSTED moved to insert a reference to optical practitioners. He said that the White Paper set forth a temporary scheme which provided for the optician being the normal sieve through which the patient passed in order that eye diseases might be identified. The medical ophthalmologist was in reserve. As soon as the Minister was satisfied that adequate ophthalmic services were provided in any area through the specialist clinics he might wind up this supplementary scheme, and the nation would get the main scheme providing for first-class ophthalmologists as the first sieve through which the patient passed. The two schemes had unfortunately been presented by some people in the form of a conflict between the medical profession and the optical profession. There were at the moment 500 ophthalmologists recognized as specialists. There were probably the same number of medical practitioners with some specialist knowledge of eye diseases. He doubted whether the Minister could ultimately get many more than 1,000 first-class medical ophthalmologists or one for every 45,000 people. He did not think that in any reasonable time the manpower position would permit the introduction of what the Bill intended to be the main scheme. Circumstances would compel the Minister to keep to the subsidiary scheme for a large number of years. He believed there were something like 7,000 opticians in the country. There was no statutory register. He asked the Minister to make proper provision for the optical profession in the Bill, and to encourage that profession to go forward with education, examinations, and a statutory registration.

Mr. SOMERVILLE HASTINGS said the Minister would be able to make full use of all the ophthalmic opticians and the ophthalmic surgeons, who should work as a team. The head of the am ought to be the ophthalmic surgeon working from a hospital with a big clinic and with assistants under him. The ophthalmic opticians should work with him not only in the hospital clinic but in the health centres. These centres should be outposts of the central clinics run by ophthalmic opticians so that sight could be tested at them by these opticians, and difficult cases could be sent at once to the ophthalmic surgeon. Mr. Hastings did not think that when the scheme was fully developed there would be room for the general practitioner who could not be a real expert in ophthalmic work. In reply to Mr. WILLINK, Mr. Hastings explained that in his parlance an optician was a man who made spectacles while an ophthalmic optician was a man who prescribed spectacles, could test errors of refraction, and could examine eyes to make sure there was no serious trouble with which he was not capable of dealing.

Mr. BEVAN said he found little to disagree with in these speeches. In the ideal system anyone having something wrong with his eyes should go first to the person who knew most about the subject. The eye specialist would not waste his time doing refraction work. Eye specialists had told him that the refractionist could do this work better than they could. He proposed to use the services of the qualified optician to the utmost extent. There was no antagonism between the spectacle-maker, the refractionist, and the specialist, but merely a proper division of functions. It would be disastrous to give an impression that the Ministry was not anxious to promote the status of eye-testing opticians. Representatives of the eye specialists and the eye-testing opticians would meet in the following week at his invitation to discuss the relative status of both sections. The results would be incorporated in the Bill. He contemplated a system where the eye specialist would be centred on the hospitals but would move freely between the health centres and the hospitals, discussing and generally supervising the work which the eye-testing optician was doing. By the time they had enough qualified eye specialists the relation between them and the eye-testing opticians would have been regularized. The independent optician was not excluded from the scheme. Mr. Linstead withdrew his amendment and Clause 41 was added to the Bill.

DISQUALIFICATION OF PRACTITIONERS

On Clause 42 Mr. PIRATIN moved an amendment to change the permissive part of the Clause into an obligation. The Clause as presented suggested that only in the case of representations from an executive council must the case be heard and it was left to the option of the tribunal whether the case of any other person should be heard. He proposed to put down later a new clause introducing a local body to which people could go in the first place.

Mr. BEVAN said the new clause would be considered when Mr. Piratin moved it. The proposed amendment would clutter up the work of the tribunal with minor complaints which the local executive committee could consider. The Ministry did not want this tribunal to be a source of petty persecution of the profession. Minor allegations would be sifted first by the local executive. If there was found to be substance in them the executive council could take serious steps against the doctor concerned, and the tribunal itself would consider whether a doctor should be removed from that list or all lists, or what should be done with him.

Dr. CLITHEROW pointed out that Clause 42 referred to representations being made to the tribunal "by an executive council or any other person." He asked Mr. Bevan to say what was meant by those words. Mr. BEVAN replied that if a complainant felt his complaint had not been adequately dealt with by the executive council he could appeal to the tribunal, which might consider the matter. If the tribunal was satisfied that the complaint was trivial or that a sound judgment had been reached it would not make further inquiries. Mr. Piratin withdrew his amendment.

APPEAL TO THE HIGH COURT

Mr. HOPKIN MORRIS moved to leave out the subsection dealing with an appeal to the Minister from any direction of the tribunal and to substitute:

Any person aggrieved by a direction of the tribunal either under the preceding subsection or under subsection (7) of this section may within three months after the date on which notice is given to him by the tribunal of their direction appeal against the direction in manner provided by rules of court to the High Court, and in any such appeal the High Court may give such directions in the matter as it thinks fit.

Dr. MORGAN hoped that Mr. Bevan would accept this amendment or look into the matter again. Until recently government departments, when they had not enough evidence to take a case to court, took it to a non-judicial body and threw on that body the onus of a decision which meant the ruin of a man's life—the decision of erasure and the possibility of not being able to practise.

Mr. BEVAN wished to prevent the Committee from being stampeded by emotions over a related subject which had nothing to do with what was before the Committee. The General Medical Council procedure might or not be altered; but that was not a matter for this Bill. The Committee was not discussing whether a man had been guilty of unprofessional conduct but whether a person who had contracted to carry out certain duties carried them out satisfactorily. He had thought first that in creating a service in which most of the doctors would participate there should be exceptional protection to the individual doctor against injustice. He had considered the existing machinery not adequate for that purpose though it worked to the satisfaction of the profession. Under the machinery the local committee considered complaints and appeals were made to the Minister. Doctors had not complained about this, but it had seemed to him that the Minister ought to put another body between himself and the local executive council. If the complaint were made against the doctor on a professional basis the G.M.C. would consider it as well as the Minister. The Minister would not consider the matter from the point of view of the doctor's position on the Register. A doctor might be continuously drunk and not attend to his work. That complaint was investigated in the first instance by a body on which the profession itself had half the representation. The other half of that body would be drawn partly from the Minister's nominees and partly from the local health authority. That executive council, after hearing the person concerned and what the doctors had said about that person, would say that they did not want him in that area. He could then appeal to the tribunal with evidence on oath, personal appearance, and all the panoply of judicial investigation. If the tribunal also said that the doctor ought to be removed from the list and he was still aggrieved he could come to the Minister. Reference to the Minister implied the right of the House of Commons to interrogate the Minister on how he was using his powers. The Minister would make an investigation, and if he decided that all the other bodies were right the man would be taken off the list. It was flat nonsense to assume that a judge of the High Court was a better person to decide whether a

CROOKES VIVOMIN

*A pleasant food supplement
for Motherhood*

A pleasant food supplement which is invaluable to nursing and expectant mothers. A specially balanced food of cocoa, malt extract and sugar, Crookes Vivomin contains the vitamins and minerals essential for the health of women during the important periods of pregnancy and lactation.

For expectant mothers we recommend 1 teaspoonful and for nursing mothers 2 teaspoonfuls, which, when mixed with hot or cold milk, makes an extremely palatable beverage.

Iron requirements of the Human Body

Iron is an essential for life—a vital element in the formation of haemoglobin. Physiologically, need for it is greatest during adolescence, through the menarche, and in pregnancy and lactation. Iron deficiency anaemias are most likely to occur during these periods. Since iron can be utilized only after it has been reduced to the ferrous state, 'Ribothiron' Tablets are especially indicated in restoring and main-

taining the iron requirement of the patient. Each tablet contains ferrous sulphate, 3 grs., together with Vitamin B₁, (thiamine hydrochloride) 0.2 mg., and Vitamin B₂, (riboflavin) 10 micrograms. These vitamins are particularly helpful, as in many cases of anaemia there is a concomitant deficiency of these Vitamin B factors. 'Ribothiron' Tablets are green-coated and are supplied in bottles of 40 and 100. Sharp and Dohme Ltd., Hoddesdon, Herts.

'Ribothiron'

ARRESTING *The Male Climacteric* BY PERORAL HORMONE THERAPY

The mental fatigue and diminished bodily energy which characterise the male climacteric respond readily to male hormone therapy in the form of ORAVIRON (British Schering brand of methyl testosterone in tablet form). Depression and nervous instability are eliminated, and the general condition, both mental and physical, shows a steady improvement.

'ORAVIRON' is presented in tablet form in the following sizes: TUBES of 20 x 5 mg tablets • TUBES of 20 x 10 mg tablets • BOTTLES of 100 x 5 mg tablets • BOTTLES of 100 x 10 mg tablets.

doctor had carried out his job properly than the executive of the profession, tribunal, or the lay Minister. Suppose a doctor were recommended by the local executive and the local tribunal not to practise in that area, and the High Court then said he must have a job there, that doctor had to become a protégé of the Ministry. If the procedure laid down by the Bill had not been carried out or if the various tribunals had exceeded their powers, or if "the principles of justice had been offended" the appellant could still go to court. Doctors themselves would be worse off, because if a doctor went to a court the case would be publicized throughout the country, whereas under the procedure in the Bill it would only be necessary to move the doctor from a particular list. He could go elsewhere, be inscribed on another list, start afresh, and probably recover himself.

Sir H. MORRIS-JONES said the penalty provided by the Clause was almost as severe as that of the G.M.C. when dealing with professional misconduct. A medical man who was driven out of service under the Bill was virtually driven out of the profession. That was the main difference between the Bill and the existing national insurance scheme which dealt only with a third of the population. Mr. LINSTAD said hitherto the main disciplinary tribunal for the doctors, dentists, and pharmacists had been their statutory body. Under the Bill the Minister, or the tribunal, would possess powers as substantial and as comprehensive as the powers of the statutory professional disciplinary bodies. It would be a matter of chance whether a drunken doctor was brought before the G.M.C. for removal from the *Medical Register* or found his way to the tribunal. If the complaint came through the professional tribunal it could ultimately reach the High Court. In any event dental and pharmaceutical cases went to the High Court. If there were two channels for discipline they should be brought to a head at one and the same point. That should be the High Court.

Mr. HASTINGS regretted that he must agree with the Minister. To determine whether an individual was fit to remain a member of the service could not be the function of the High Court. Those employed in this service would have under the Minister's proposals all they needed against injustice or victimization. Mr. REID said that Mr. Bevan's argument could only have validity if the Minister believed there would still be a large amount of private practice by which a man who retained his professional status but not his place on the list could earn his livelihood.

On a division the motion that the words which Mr. Hopkin Morris proposed to be left out should remain part of the Clause was defeated by 17 to 19. This was the first defeat of the Government during the Committee Stage of the Bill. A division immediately followed upon whether the words which Mr. Morris proposed to insert should be added to the Bill. This motion was defeated by 16 to 17. After an adjournment the chairman, Mr. BOWLES, suggested that nothing further should be done at that stage on Clause 42.

Mr. REID saw no reason why the Committee should not go on with the Clause as it stood, and subsequently he could consider whether other steps should be taken at a later stage. The medical profession would not thank those who had defeated the Government for the extraordinary situation which resulted.

JUDICIAL INVESTIGATION

On the motion of Mr. KEY the Committee accepted an amendment to bring about reciprocity with Scotland on the disqualification of practitioners. This provided that where doctors were totally disqualified from inclusion in the list in Scotland they could be disqualified from the list in England, but if they were disqualified in only one or two places in Scotland they would not be disqualified from the list in England.

Mr. PIRATIN withdrew a further amendment on receiving an assurance that the person concerned would have a hearing before the tribunal. Mr. BEVAN said that if there were a hearing the person must attend.

On the motion that the Clause as amended stand part of the Bill, Mr. REID said that although Mr. Bevan had spoken of the full panoply of judicial investigation the right of a person to appear by solicitor or counsel before the tribunal was not covered, and he doubted whether the right of a tribunal to take evidence on oath was covered even by implication. Capt. BAIRD said the executive and the higher authorities could impose only one sentence. He hoped the Minister would consider giving them the right to admonish or to impose some minor punishment.

Mr. BEVAN said it was proposed to make provision by regulation for evidence to be taken on oath and for legal representation. It was also proposed by regulation to enable other forms of discipline to be imposed by the executive council and the tribunals in addition to that of removal from the list. Smaller penalties would be appropriate for minor offences.

The Clause as amended was ordered to stand part of the Bill. Clause 43 on the powers of the Minister where services are inadequate was also added to the Bill. Mr. BEVAN said that where the service had broken down the executive council would consult the representatives of the services before making any proposals. He did not wish to tie the executive council to formal discussions because urgent action might be necessary.

Clause 44, which concerns the recovery of charges in respect of certain appliances and dental treatment, was ordered to stand part of the Bill.

OTHER CLAUSES

Discussing Clause 45 on the exercise of choice of medical practitioner in certain cases, Mr. BEVAN explained that the Clause would apply when patients were themselves too ill to choose a doctor or in the case of children where the choice would be by the parents as legal guardians.

On Clause 46 the Committee negatived an amendment proposed by Mr. PIRATIN to the effect that charges for the use of health centres should not be paid by general practitioners. Mr. BEVAN said that when a doctor was taken away from his consulting room and was given one at the health centre he had not the same expenses to meet. It was therefore reasonable to expect him to make some small payment. He would be asked to pay not an economic rent but a reasonable rent. The rents charged would not be such as to discourage him from going there.

Mr. HASTINGS said a doctor coming into an area would have no surgery and would be prepared to pay something instead of starting a surgery for himself. On the other hand a doctor already in an area who proposed to carry on a certain proportion of private practice would need a surgery. Dr. STROSS said there would be great advantages to the doctor at the health centre, not only to himself but to his wife and family, because he might be able to live as a private person when not at work. A doctor's house was often on a dusty and noisy main road and was the last place where he would live if he could live somewhere else. Medical men had no incentive to go into a health centre and pay another rent while still compelled to live in the large house they already had. They were not allowed to sell that house to another medical man, having sold their goodwill to the Minister. If they sold it for any other purpose they were likely to lose a substantial amount of money. That point exercised the minds of family doctors all over the country. Mr. MCGHEE said the Minister ought to allow doctors to use the health centres freely but to make them provide their own staff.

Mr. BEVAN said he would be foolish to attempt a precise indication of what he thought health centres would be like. Doctors were allowed substantial expenses on account of having to provide facilities in their houses, and that expressed itself in the standard of remuneration. He thought that before long, if good health centres were provided, the doctor's wife would have something to say about it. He could not understand why a doctor's wife should continue to be tormented and have to be at the telephone day and night when her husband could get better facilities at a health centre. He believed that the financial inducements, together with the amount of wholesome nagging which would come in course of time, would enable the Ministry to get the doctors into the centres. At the same time the Committee must remember the patients. There had been a tendency to think that the Committee was providing a service for doctors, dentists, ophthalmic surgeons, and opticians, and to forget the patients. The doctors at the health centres would be able to arrange for emergency calls, but he agreed that continuity of treatment by the same doctor for the same patient was necessary. The Committee was not handing the patients over to a team of doctors at the health centres. The Ministry would have to feel its way for a considerable time in the organization of the health centre service. Clause 46 was ordered to stand part of the Bill, as was Clause 47 on the decision of disputes.

On Clause 48, which provides courses for dental and medical practitioners, Sir HAROLD WEBBE moved to bring in optical practitioners for these facilities, and Mr. LINSTAD urged the inclusion of pharmacists. Mr. BEVAN said that if the language of the Bill did not give him power to provide such facilities then language would be used which would do so. Sir HENRY MORRIS-JONES said the facilities proposed extended what already existed under the National Insurance Act. The rural practitioners would welcome this extension, but he thought that Mr. Bevan had not made provision for locum tenets to be provided when doctors left their practices for refresher courses.

Mr. BEVAN said that when a doctor was taken from a rural area to attend a refresher course the executive council in that area would be under an obligation to provide a substitute. Sir H. Webbe withdrew his amendment. The Clause was added to the Bill and the Committee adjourned.

MENTAL HEALTH SERVICES

On June 27 Mr. KEY moved an amendment to Clause 49. In the provision transferring to the Minister the administrative functions relating to the reception of persons suffering from mental illness as private patients, he moved to leave out the words "as private patients." This was a necessary drafting amendment; it might be required that the Minister should arrange for treatment in a certified institution of a patient who would normally be treated in a hospital vested in the Minister. Such a patient would not be regarded as a private patient.

The Committee agreed to the amendment, and also to another proposed by Mr. KEY to ensure that both Sections 23 and 24 of the Mental Deficiency Act, 1913, providing for the appointment of officers by the Board of Control and for their disqualification, should cease to apply to any officers other than the secretary and inspector. Mr. KEY moved further to add "commissioners" after "inspectors." He said Section 24 of the Mental Deficiency Act disqualified from office any commissioner, inspector, secretary, or officer of the Board who was directly or indirectly financially interested in certified institutions, houses, and private homes for mental defectives, and so on. The transfer to the Minister of the offices of the Board other than commissioners, inspectors, and secretary made it necessary to preserve this disqualification only in the case of commissioners, inspectors and secretary. The amendment was agreed to.

Mr. REID asked whether Mr. KEY could indicate the appointed day when this Clause came into force. Mr. KEY said he could not; it would be a case of seeing how the administrative business arose. The Clause as amended was ordered to stand part of the Bill.

On Clause 50, repealing and amending the lunacy and mental treatments Acts and the mental deficiency Acts, Mr. KEY moved to insert words "enabling the Minister as a temporary measure to include in the designation of a mental hospital a small poor law institution in which only mental patients were accommodated or the separate wards of a poor law institution that were so used." The result would be that temporarily patients accommodated in such places would come under the care of the medical and nursing staff of the neighbouring mental hospital, and the hospital management committee responsible for their maintenance would be that of the mental hospital. The poor law authorities would cease to have any statutory responsibilities or duties towards these people. Mr. WILLINK remarked that this was the first reference in the Bill to a mental hospital. The Committee agreed to the amendment.

Mr. KEY moved to omit from subsection 4 of Clause 50 words restricting the transfer of a mental patient from a workhouse to a mental hospital or institution for defectives in the particular regional area. The convenience of patient and relatives should be considered so that he could be transferred to another institution even if it happened to be in another regional area but nearer his home. He assured Mr. REID that he power would not be abused to take people further away from their relatives merely for administrative convenience. The Committee agreed to the amendment and also to a proposal by Mr. KEY to omit subsection 5 of Clause 50, which permits the continued use as a special school of an institution for defectives. Mr. KEY explained that a new Clause would be moved to replace this subsection. Clause 50 as amended was ordered to stand part of the Bill; also Clauses 51, 52, and 53.

EXPENDITURE BY REGIONAL HOSPITAL BOARDS

On Clause 54 Sir H. LUCAS-TOOTH asked the Government to state its intentions. Mr. WILLINK said it did not seem from what Mr. BEVAN had said that there would be maximum initiative and personal life in the hospital management committees, and in the boards of governors of teaching hospitals. If these authorities feared that money not spent in one year might be taken from them in the next year, that would make for inefficiency.

Mr. KEY said the idea of the Ministry was that the hospital management committee would give the regional board for its area an estimate of its expected expenditure in the coming twelve months. That would be in some detail to give the regional board an idea of the character of the service to be carried out and the extent of the development proposed. The regional board would be able to negotiate with the hospital management committees and to suggest an extension here or a modification there for the time being. In the end the regional board would submit to the Minister an appreciation of the contemplated expenditure in its area during the next twelve months. That would be analysed, and would be subject to the Minister's approval. He must decide whether a region was carrying out its functions as it should, and whether it was exceeding what should be done at that particular time, if the service as a whole was to be adequately financed. The expendi-

ture having been approved, the regional board would have its annual amount of money and would allocate to the hospital management committees their proportions of the regional sum. In the expenditure of that money regional boards and hospital management committees should have considerable latitude. If a deficit resulted from something unforeseen it would have to be made good in the budget arrangements of the following year. Any surplus must be carried through to the next budget period.

The Clause was ordered to stand part of the Bill, as was Clause 55, with drafting amendments.

RESPONSIBILITY OF THE MINISTER

On Clause 57 Mr. REID moved to omit the medical practices committee and the dental estimates board from the authorities in connexion with which the Minister is empowered to make an order declaring them to be in default, and directing them to discharge their functions as the order may specify. The medical practices committee had been represented as a body of some independence, appointed by the Minister but not the Minister's agents. The Minister would undermine their independent status if he took the drastic powers proposed. In the next amendment on the paper Mr. BEVAN would propose with regard to these bodies and others that their members should forthwith vacate their office, and that the Minister would then carry on until someone else was appointed. He had made no provision for a public inquiry. The procedure was too summary and unlimited.

Mr. BEVAN said the Committee could not have two opposite principles, that was to say Parliament imposing the responsibility on the Minister to provide a service, and then creating an independent body in the service which could refuse to carry it out. These powers were necessary. In practice they would not be exercised summarily. If the Minister of Health set aside the medical practices committee without considerable discussion there would at once be a first-class debate in the House of Commons. Col. STODDART-SCOTT said that under the Clause as it stood if a teaching hospital failed to carry out one of the Minister's directions he could sweep away the privileges given to it without any inquiry whatever. The words proposed to be left out by Mr. REID were ordered to stand part of the Bill by 27 to 13. Mr. KEY then moved the amendment previously mentioned by Mr. REID to provide that except where the body in default is a local health authority its members shall forthwith vacate their office. After discussion the amendment was agreed to. Further amendments were made and the Clause as amended was ordered to stand part of the Bill. Discussion then followed on Clause 58, on the acquisition of land, which with an amendment was also approved.

GIFTS AND INTERIM DIFFICULTIES

Mr. WILLINK moved on Clause 59 to add hospital management committees to the bodies who are to have power to accept, hold, and administer property upon trust for purposes connected with hospital services. Mr. HASTINGS saw a danger in the amendment, and Dr. MORGAN hoped the Minister would not accept it.

Mr. BEVAN said it was intended that a proper proportion of the endowment fund should be allocated to the management committee. That committee was the body which would "warm up" the whole administration and maintain proper relationship between the hospital itself and the doctors and staff. But the Ministry wanted the system to be integrated. It seemed to him that it ought to be possible for the hospital management committee to take gifts because if not it was unlikely the gifts would go to the regional board. He agreed with the principle of the amendment and asked Mr. Willink to withdraw it on the understanding that on the Report stage it would be included. Mr. Willink withdrew the amendment.

Mr. LIPSON drew attention to the difficult financial position in which the hospitals would find themselves during the interim period. He urged the Minister to explain in a public appeal that under the State service the hospitals would still be the hospitals of the people, and that it was necessary to maintain them; and that there would be opportunities for the public to add to what the State was doing. He asked Mr. BEVAN to make clear that he was taking over the endowments only once, and that future gifts would be allowed to be retained.

Mr. BEVAN said the financial difficulties into which the hospitals were getting were not a result of the Government proposals. He admitted that knowledge that future provision for voluntary hospitals would be made by the State must freeze the flow of charitable endowments, but he hoped it would not have that effect too much in the next eighteen months. He appealed to people to support the hospitals in the intervening period. He could not give a guarantee that hospitals would be allowed in the future to keep all the money that went into

them, because no Parliament could bind another Parliament. It would take some time to disentangle the subterranean assets which the hospitals concealed all the while. The hospitals had run persistent overdrafts and detained considerable assets at the same time, the overdrafts being the vacuum into which they hoped to suck charitable endowments.

The Clause was ordered to stand part of the Bill, as was Clause 60 on the power of trustees to make payments to regional hospital boards and boards of governors.

QUALIFICATIONS AND REMUNERATION

On Clause 62 Mr. REID proposed to delete the provision that regulations may be made with respect to the qualifications of any officers employed by any body constituted under the Bill or employed by a local health authority or a voluntary organization mentioned in the Bill. He doubted whether the Minister appreciated that under the Clause he could make regulations with respect to the qualifications of doctors.

Mr. BEVAN said no Minister would try to meddle with the qualifications of doctors. Mr. SOMERVILLE HASTINGS said that for some doctors qualifications were required. Many local authorities thought it essential that medical officers of health should have the D.P.H.

Sir HENRY MORRIS-JONES said the only qualification which should be recognized was that a man was a fully qualified and registered medical practitioner. Mr. BEVAN said that nobody was interfering with that, and the amendment was negatived. Clause 62 was added to the Bill.

On Clause 63 Mr. COLLINS raised the position of certain mental hospital workers who were dealt with by the Asylum Officers Superannuation Act, 1909, which enabled them to retire at the age of 55. Mr. BEVAN said that where these people had a superior entitlement provision would be made to preserve it.

Mr. WILLINK moved an amendment on Clause 64 to provide for compensation for officers who had worked under contributory schemes linked with a group of hospitals. Mr. BEVAN resisted the amendment but guaranteed that the Minister of National Insurance and he would do their utmost to absorb these people into the new service. The proposed amendment was rejected by 12 to 19.

Further amendments were made on the motion of Mr. KEY, and the Clause as amended was ordered to stand part of the Bill. So were Clause 65 with amendments, Clause 66, and Clause 67, the latter with an amendment to ensure that the relevant section of the Public Health Act, 1875, was properly applied.

On Clause 68 the Committee accepted an amendment by Mr. KEY, and the Clause so amended was ordered to stand part of the Bill.

Specialists due for Release

Mr. BOWDEN inquired on June 27 whether Mr. Bevan knew that, through the failure of the Central Medical War Committee to call up specialist medical officers at a rate quick enough to replace those specialist medical officers in the Services who were due for release, it had been necessary to retard the release of these medical officers. He asked the Minister to speed the call-up of those specialists who were eligible for service, in order that serving medical officers could be released.

Mr. BEVAN said he was aware of the difficulty. His department was in close touch with the Central Medical War Committee, who, he was satisfied, were making every effort to find replacements for specialists due for release.

Tuberculosis Service

Sir THOMAS MOORE asked on June 27 for a statement on the future of the tuberculosis service; and how far the policy of the Minister of Health was in accord with the policy of the Joint Tuberculosis Council.

Mr. BEVAN said the new service would provide all facilities for handling tuberculosis, mainly through the new hospital and specialist services backed by all the supplementary domiciliary services of the local authorities. He added that he could not commit the Joint Tuberculosis Council.

Mr. SPARKES reported on June 27 that there were 600 cases waiting for admission to Middlesex County Council tuberculosis hospitals; that 200 beds were closed through shortage of staff, due in some measure to lack of suitable accommodation for them. He asked why Mr. Bevan declined to approve plans for new nurses' homes and extensions to the Harefield Hospital.

Mr. BEVAN said he knew of the shortage of beds for tuberculous patients in Middlesex, and of the difficulties raised by inadequate staff accommodation, but must have regard also to other pressing claims on building labour and materials. He was reviewing the case to see whether a part of the proposed building might proceed.

Medical News

Dr. Thomas Clarence Routley, General Secretary of the Canadian Medical Association, was appointed C.B.E. (Civil Division) in the Canadian Dominion Day Honours List published on July 1.

A meeting of the Pathological Society of Great Britain and Ireland is being held at the University of Aberdeen on Friday and Saturday, July 5 and 6.

Sir Francis Fraser, M.D., will deliver the Frederick Price Lecture in the hall of the Royal College of Physicians of Edinburgh on Friday, July 12 at 5 p.m. His subject is "Postgraduate Education and the National Health Service."

The Harben Lectures for 1946 will be given on Monday, Tuesday, and Wednesday, July 15, 16, and 17, at the Royal Institute of Public Health and Hygiene, 28, Portland Place, W.1, by Dr. William H. Feldman, of the Mayo Foundation, University of Minnesota. The general subject of the lectures is the chemotherapy of tuberculosis, including the use of streptomycin. The first lecture will be on the basic considerations of chemotherapy in tuberculosis; the second, an evaluation of the efficiency in tuberculosis of sulphonamides, sulphones, and certain other substances; and the third, on the effect on tuberculosis of antagonistic substances of microbial origin, with particular reference to streptomycin. Admission is free without ticket, and each lecture will begin at 3 p.m.

The Nutrition Society, with the help of the British Council, has organized an informal post-war conference of European Nutritionists, to be held in Great Britain between July 4 and 20, to enable research workers in ex-occupied territories to re-establish contacts with their colleagues in this country. The following open meetings, all of which will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., are included in the programme: Friday, July 5, 2.30 p.m.; Saturday, July 6, 10.30 a.m. and 2.30 p.m.; Monday, July 8, 10.30 a.m. and 2.30 p.m. These open meetings will be devoted mainly to papers by visiting scientists, describing nutritional conditions and investigations in their own countries during the war. All members of the Nutrition Society are invited to attend.

The annual meeting of the Medical Insurance Agency was held at B.M.A. House on June 14, with Sir Robert Hutchison in the chair. Sir Hugh Lett and Dr. L. G. Glover intimated their desire not to be re-elected to the Committee of Management; and the committee accepted these decisions with regret and with an expression of thanks for their past services. Sir Henry Tidy, Mr. A. M. A. Moore, F.R.C.S., and Mr. Ronald Raven, F.R.C.S., were elected to the committee; Lord Horder, Dr. Alfred Cox, Dr. J. A. Brown, Dr. James Fenton, and Dr. R. W. Craig were re-elected. Allocations to the Royal Medical Benevolent Fund and to the Royal Medical Foundation of Epsom College totalling about £5,600 were approved from the disposable surplus on last year's working. Sir Francis Fraser was appointed to the Conjoint Committee of Epsom College to represent the Agency should an invitation to do so be received. The proceedings ended with a vote of thanks to the chairman and to the honorary secretary, Dr. Henry Robinson, for their work during the past year.

A delegation of six scientists and educationists from the Netherlands is visiting this country for three weeks under the auspices of the British Council to make contact with British colleagues in London, Oxford, and Cambridge.

Films of microbiology and protistology made under the direction of Dr. Comandon by the Département de Cinémicrographie, Institut Pasteur, Garches, S. et O., have been brought to this country by M. Pierre de Fonbrune. They include those reviewed recently in the *British Medical Bulletin* (1946, 4, 72); and also films on *Amoeba verrucosa*, Karyokinesis, and *Lankesterella*. They are silent films on 35 mm. stock with captions in French. A selection of these films will be shown in London by the British Council at 5 p.m., on Monday, July 15. A limited number of seats are available and will be allotted in rotation on application to the British Council, 3, Hanover Street, London, W.1. Telephone: Mayfair 8484, extension 134.

At the Annual Meeting of Fellows of the Royal Society of Medicine on July 2, Group Capt. Antoni Fiumel, late D.G.M.S. to the Polish Forces, and Col. C. F. Koch, late D.G.M.S. to the Netherlands Forces, were admitted as honorary Fellows. Both Group Capt. Fiumel and Col. Koch escaped from their countries to Great Britain in the early part of the war. The other honorary Fellows elected are: Col. L. C. Montgomery, R.C.A.M.C., Sir Alan Newton, F.R.A.C.S., F.R.C.S., and Col. W. S. Middleton, U.S.A.M.C. Diplomas of Fellowship are being presented to Col. Montgomery and Col. Middleton by the President of the R.S.M., Sir Gordon Gordon-Taylor, at present on tour in the United States and Canada. Sir Maurice Cassidy has been elected president of the Society for the session 1946-7.

No. 24

EPIDEMIOLOGICAL NOTES

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 15.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Discussion of Table

In England and Wales 519 more cases of measles were notified than in the preceding week. The incidence of other infectious diseases declined, the chief falls being whooping-cough 124, scarlet fever 121, and diphtheria 42.

The decline in whooping-cough was most notable in Staffordshire 63 and Lancashire 57. In the south the incidence increased, and the combined counties of the south-east and south-west regions had a rise of 75 cases.

The only local variation of any size in the returns for scarlet fever was a decrease of 42 in Yorkshire West Riding.

London and the four surrounding counties had almost two-thirds of the total cases of measles. The largest rises were Middlesex 193, Surrey 90, Kent 70, Essex 64, Lancashire 56, Southampton 51; an exception to the general rise was a decrease of 54 in Yorkshire West Riding. Only 262 cases of diphtheria were notified. During the preceding five years 1941-5 the lowest weekly total recorded in each year was 674, 572, 493, 398, and 346. The largest falls in diphtheria during the week were Lancashire 21 and Durham 11.

The largest returns for dysentery were Lancashire 46, London 20, Kent 14.

In Scotland an increased incidence was recorded for scarlet fever 23, diphtheria 14, and dysentery 12. The rise in diphtheria was due to scattered cases. The increase in dysentery was contributed by Glasgow, where the cases rose from 4 to 23.

In Eire the only variations in the trends of infectious diseases were decreases—measles 12 and whooping-cough 17. Of the 28 cases of whooping-cough 26 were notified in Dublin C.B.

In Northern Ireland whooping-cough declined by 17; all the cases were notified in Belfast C.B.

Week Ending June 22

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 941, whooping-cough 2,026, diphtheria 274, measles 4,516, acute pneumonia 496, cerebrospinal fever 51, dysentery 93, acute poliomyelitis 13, paratyphoid 1, typhoid 4

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Alitology Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ANY QUESTIONS?

Bone and Joint Tuberculosis in Children

Q.—What are the advantages of the Swiss treatment of bone and joint tuberculosis in children? Is the treatment itself more or less standardized in England and in Switzerland, and does the only difference lie in the climate?

A.—The principles governing the treatment of bone and joint tuberculosis are the same whatever the joint involved and are largely independent of the age of the patient. They are as follows: (1) general treatment, fresh air, sunshine, good food, rest, and congenial occupation; (2) strict immobilization of the affected part, which may have to be continued for a long period after the disease has become quiescent, more especially if the affected part is weight-bearing; (3) as a terminal procedure, when the local lesion is no longer active, arthrodesis is often of value in converting an unsound fibrous into a sound bony ankylosis, thus rendering external splinting unnecessary; (4) it is occasionally possible to excise a localized bone lesion, but even in such a case general treatment is still necessary since the patient, and not merely the affected limb, is tuberculous.

The writer is not sufficiently familiar with the practice of all the main centres in Switzerland to say dogmatically whether

or not methods of treatment in that country are standardized. In England there is fairly general agreement about the principles of treatment, though there are differences of emphasis and in details of technique as between one centre and another. This is only to be expected, since our understanding of the vagaries of this serious disease is still incomplete; standardization in the absence of full knowledge would indicate stagnation. It is not unreasonable to suppose that Swiss surgeons, whose competence is generally acknowledged, are no more slaves to uniformity than we are. The writer's impression is that British surgeons, on the whole, are more strict in their methods of immobilization, and more in favour of terminal arthrodesis. There is an undoubted difference in the climate, and it is popularly supposed that the alpine sun is endowed with magical powers of healing. It certainly is not in other parts of the world where people see more of the sun than we do. All forms of tuberculosis occur with some frequency in the Kenya highlands, in South Africa, in Australia; and in the Mediterranean countries. Gauvain and Girdlestone, among others, believe, probably rightly, that variability in climate is more stimulating and beneficial to the patient than steady solar irradiation—in which case nothing could be better than the English climate, the only constant feature of which is its irregularity.

Patients with bone and joint tuberculosis recover well in hospitals in Switzerland and in the British Isles; some die in Switzerland; some die here. Reliable comparative figures are unobtainable. What is disturbing is that patients who appear to have made a good recovery in Switzerland sometimes relapse very rapidly after returning to England. The writer is not alone in believing that the best course is to treat the patient in the climate in which he will have to live subsequently, and if one of his own children had the misfortune to develop bone tuberculosis he would insist on the treatment being carried out in England.

Protein Hydrolysates

Q.—*Is protein hydrolysate useful in the treatment of selected cases of duodenal ulcer?*

A.—Although certain workers in the United States have shown enthusiasm for the treatment of duodenal ulcer with protein hydrolysates there is no clear indication for such a line of treatment, for the digestive and absorptive power of the gut is not seriously impaired. The clearest indication for the use of protein hydrolysates is in those relatively few conditions where the power to ingest, digest, or absorb protein is so adversely affected as to constitute a serious danger to convalescence.

Hyperhidrosis and Bromidrosis

Q.—*What are the causes of bromidrosis as distinct from hyperhidrosis?*

A.—Hyperhidrosis indicates an increased secretion of sweat, either general or local. Local forms express a state of physiological instability, often of emotional origin, and affect axillae, palms, and soles, but may be more widespread. Generalized hyperhidrosis is more usually the result of fever or general illness or of climatic and environmental conditions.

Bromidrosis may or may not be associated with hyperhidrosis and is of two main types. The first is the consequence of a macerated hyperkeratosis, which may accompany hyperhidrosis of the hands and feet, and some degree of bacterial infection of this macerated tissue. The most effective treatment is by small doses of luminal internally and the use of sodium hexametaphosphate locally, as a foot-powder or as a foot-bath in a strength of 10% or so. Bromidrosis may be a natural occurrence in women, particularly affecting the axillae, pubic, abdominal, and breast regions, and is connected with the activity of the apocrine glands in these sites. These are large sweat glands opening into the pilo-sebaceous follicles and related to the odoriferous glands of animals. Bromidrosis is sometimes checked by the administration of oestrogens.

Essential Hypertension

Q.—*A very plethoric woman aged 48 had a sudden hemiplegia eighteen months ago. She has completely recovered from the paralysis and now has attacks of giddiness with blurring of vision lasting several hours. The blood pressure is 230/180 mm. Hg. The urine contains no albumin. There*

is slight improvement with phenobarbitone and theobromine. Is venesection contraindicated in view of the past history of hemiplegia? Would the administration of thiocyanate be of any use? If not, apart from "taking it easy," is there any other treatment?

A.—One of the chief prognostic features in such a case would be the condition of the fundus oculi and the presence or absence of retinal haemorrhages (which are of very grave significance). Renal function tests are also advisable in a case like this, and if the results are not grossly abnormal the question of abdominal sympathectomy will arise for serious consideration. The decision is one which calls for the most deliberate consultation by physicians and surgeons with experience of this measure. Of medicinal remedies, thiocyanate is certainly worth a trial as being one of the few drugs which will reduce a raised blood pressure. It is a remedy to be used with caution, however, and over a short period only, as toxic symptoms are by no means uncommon. Venesection has but a transitory effect upon the blood pressure, and, in the absence of any clinical symptoms suggesting acute cerebral oedema, seems scarcely to be indicated.

Counting Spermatozoa

Q.—*How does one count spermatozoa? What are the upper and lower limits of a normal count?*

A.—It is usual to employ the Neubaur counting chamber and white blood cell pipette. Various diluted fluids are used, some containing stain, others not. Mix the semen well and fill to the 0.5 mark half-way up the pipette. Then fill the entire chamber with a solution of 5% sodium bicarbonate and 1% phenol (the phenol ensures absence of motility of the spermatozoa). This gives a dilution of 1 in 20. If the spermatozoa are few in number the dilution can be modified to 1 in 10. Having discarded the fluid from the stem of the pipette, transfer some from the bulb to the counting chamber and count the sperms in 1 sq. mm. Multiply by 10, to find the number in 1 cu. mm., and then by the diluting factor (20). Multiply finally by 1,000 to find density per ml. Some workers prefer not to use the pipette because of the difficulty of getting the semen evenly mixed. An alternative technique, using this time a diluting fluid which also stains, is as follows. Dilute the semen in bulk with an equal quantity of saline and mix well. Take 0.2 ml. of this and mix with 0.2 ml. of Lempert Kristenson's platelet solution (sod. cit. 1 g., mercuric chloride 0.002 g., brilliant cresyl blue 0.2 g., water 100 ml.). The mercuric chloride kills spermatozoa. Add 1.6 ml. of saline and mix well to obtain a dilution of 1 in 20. Fill the counting chamber and count as before.

A repeat count is desirable in each case, and more than one specimen of semen should be tested to exclude spontaneous variations. Caution is required in the interpretation of the result, and fertility cannot be assessed by sperm density only. The volume of seminal fluid, the survival capacity of spermatozoa, and their morphology, all have to be taken into consideration. Other things being equal, it is generally reckoned that good fertility is associated with a count of 100 millions per ml. and over, but any count over 60 millions is regarded as being within average limits. The tendency nowadays is to lower the standard and not to regard as indicative of significant impairment of fertility any count above 30 millions per ml. If the count is below 10 millions then fertility is extremely low, but it should be remembered that many men with counts of two millions per ml., and even less, have proved capable of producing children. For further details reference should be made to books such as *Fertility in Men*, by R. S. Hotchkiss, 1945. Wm. Heinemann Medical Books, Ltd.

Indecent Assault

Q.—*What exactly is the indecent assault which one reads of so often in the newspapers but which is not mentioned in books on medical jurisprudence?*

A.—Assaults of a sexual nature not amounting to rape or attempted rape are considered to be indecent assaults. Indecent assault is an indictable misdemeanour, and is referred to, but not defined, in the Offences against the Person Act, 1861, and the Criminal Law Amendment Acts of 1885 and 1922. These references, with one exception, are concerned with offences

against women or girls, and a charge of indecent assault is, of course, usually made in such a connexion. But it would appear that a similar charge can arise from an offence against a man or boy, for Section 62 of the Offences against the Person Act states that "whosoever . . . shall be guilty of any indecent assault upon a male person shall be guilty of a misdemeanour. . . ." In Scotland such cases would be dealt with under the common law as an aggravated form of assault, the aggravation being determined by an intent to gratify lewdness. Such intent might be present in an assault either on a female or on a male.

Penicillin Prophylaxis of Streptococcal Sore Throat

Q.—Are penicillin lozenges of any value in the prophylactic treatment of healthy children and adults who have recently been in contact with cases of (1) scarlet fever, (2) acute streptococcal tonsillitis?

A.—Although penicillin lozenges have been used with some success in the treatment of streptococcal tonsillitis, there are as yet no data on their value in the prophylaxis of sore throat and scarlet fever. One disadvantage of sucking antiseptic lozenges is that, contrary to expectation, the antiseptic is not concentrated on the tonsillar surface or on the pharyngeal wall. Experiments with tablets containing methylene blue have shown that the backward currents in the mouth carry the material along channels which largely avoid these surfaces. Partly for this reason and partly because the infecting organism gets into the tonsillar crypts, treatment of streptococcal throat infections with penicillin has lately been by systemic use of the drug. However, it may be possible by sucking lozenges to maintain a sufficient concentration of penicillin in the throat and nasopharynx to prevent invasion of the tissues by the haemolytic streptococcus, and controlled trials to this end will no doubt be carried out. There is probably less risk with penicillin of breeding drug-resistant streptococci than is the case with the sulphonamides. Penicillin-resistance cannot be induced very readily by test-tube experiments and organisms that have been rendered penicillin-resistant readily revert to the sensitive state when cultured in the absence of penicillin.

Dhobi's Itch

Q.—What is the best treatment for dhobi's itch?

A.—There is no routine treatment for dhobi's itch, as each case must be judged on its own merits, but if one remedy were to be selected in preference to others the choice would fall on Whitfield's ointment. The condition should not be overtreated, as is sometimes done, when the remedy is blamed for unsatisfactory results which are due not so much to the remedy as to its over-enthusiastic application. It may also be mentioned that the condition is sometimes diagnosed on rather slender clinical evidence, without microscopical confirmation, and in such cases the necessarily strong fungicides prove merely irritants.

Treatment of Chronic Rhinitis

Q.—A schoolmistress suffers from chronic catarrh which she attributes to long hours spent in a chalk-dust atmosphere. What is the treatment?

A.—The nasal discharge should be examined for pus cells and eosinophil cells, if necessary on several occasions. Pus cells indicate infection and eosinophil cells an allergic reaction. If pus cells and bacteria predominate involvement of one or more sinuses is likely and the appropriate investigation and treatment is required. If eosinophils predominate the catarrh is allergic in origin. Intradermal skin tests should be done and the results correlated with the history.

The commonest inhalants to cause allergic rhinitis areorris root (in face powder), house-dust, feathers, and various animal danders, while the commonest foods are wheat, egg, milk, potato, and chocolate. Chalk is not usually considered as an allergen, but as a non-specific or secondary irritant. The use of a damp duster to reduce chalk-dust at school is advisable. Foods, and where possible inhalants, suspected of causing symptoms should be completely eliminated for six weeks and the effect observed. House-dust sensitive cases are likely to benefit from "desensitization" (orris-root-free face powder, skin tests, and desensitizing solutions can be obtained from C. L.

Bencard's, Ltd.). Ephedrine gives symptomatic relief. Possibility of a psychological trigger should be fully re and a hormonal imbalance is sometimes responsible. boestrol and thyroid extract have in some cases benefited. When such measures fail, local treatment, su cauterization or ionization, should be carried out, espe when there is no superadded infection.

Soldiers' Dermatitis

Q.—I am M.O. to a small factory with employees engaged soldiering work. How can I prevent soldiers' dermatitis caused by "splashing" with Baker's solution?

A.—Baker's solution is acidic zinc chloride, and zinc chloride is the most irritating of zinc salts. Soluble salts of zinc cipitate albumin in the tissues and have a caustic action in st solution, and an astringent one in dilute solution. Zinc chloride is hygroscopic and therefore extracts water from organic tis to such an extent as to produce ulcers of the skin and of nasal septum. Cleanliness is the best method of preventing lesions. Washing facilities need to be provided and the wor encouraged to use them. Provision of barrier creams will some protection against Baker's solution—these are fully cussed by Thelwall Jones, *Brit. J. Industr. Med.*, 1946, 3, 8.

INCOME TAX

Employment: Purchase of Equipment

S. R. is a teacher of a surgical specialty. If he buys a clinical camera to assist him in this work can he claim a depreciation allowance?

****** It is assumed that S. R.'s income from this work is received in the form of payment for employment and accordingly is assessable under Schedule E. In that case he can make the claim only if he can show that the camera is "necessary" for his work. As it is normally assumed that an employing authority will find "necessary" apparatus S. R. may find the production of the required evidence impracticable.

Car Transactions

J. H. bought a car for £140 in 1939 and sold it for £275 in November, 1945, buying a second-hand car for £350. Depreciation was allowed on the old car. Can he claim any extra allowance for 1945-6?

****** In strict law such a claim can be made, because the rule that the depreciation allowance should be calculated according to the value of the car as at the date of the end of the account preceding the year of assessment did not come into operation for 1945-6. But if—as is presumably the case—J. H.'s depreciation allowance have hitherto been calculated on the usual "preceding" basis, the charge for 1945-6 might entail a revision of the allowances for previous years. The claim may not be worth while. As the car was sold before April 6, 1946, no "balancing charge" can be assessed on the "capital" profit made by the sale of the old car. For 1946-7 an initial allowance of 20% of £350=£70, and a depreciation allowance of 25% of £350=£87 10s. (i.e., £157 10s. in all) can be claimed in respect of the car bought in 1945.

LETTERS, NOTES, ETC.

Herpes Zoster and Variella

Dr. JAMES KAY (St. Helens) writes: A man, aged 42, began to have severe pain over the distribution of the second thoracic segment on the right side. Five days later the typical vesicles of herpes zoster appeared and two days after this a generalized chickenpox eruption was seen. The vesicles of the herpes were about half-an-inch (1.2 cm.) in diameter, very profuse, and associated with very severe pain. On the day the chickenpox eruption appeared 4 ml. of a liver extract was injected intramuscularly, and the effect on the herpes zoster was dramatic. The pain disappeared within twenty-four hours and the vesicles began to dry up. No fresh chickenpox spots appeared. The effect upon the herpes zoster, in view of the recent note in this *Journal* (June 15, p. 942), seems definite. The chickenpox eruption may have been mild without treatment, but it would be of interest to try the effect of similar therapy on a series of early cases of chickenpox. No rationale is offered for this line of treatment.

Penicillin Therapy Booklet

Messrs. Boots have issued a booklet entitled "Penicillin Therapy" which is intended to give practising physicians information on the principal uses of penicillin, dosage, and methods of administration. Copies may be had from the Medical Department, Boots Pure Drug Co. Ltd., Station Street, Nottingham.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 6 1946

METROPOLITAN COUNTIES BRANCH

Annual General Meeting.

The annual general meeting of the Metropolitan Counties Branch—the first such meeting since 1939—was held at B.M.A. House on June 18, Mr. A. M. A. Moore, chairman of the Branch Council, presiding in the absence of the retiring President, Sir Crisp English. At the opening of the meeting those present paid a silent tribute to the memory of Dr. A. Keith Gibson, secretary of the Branch, who died a prisoner of war in Germany in 1941.

In the report submitted to the meeting it was stated that during the war the membership of the Branch had fluctuated owing to the number of practitioners joining the Services, but the membership was now increasing and at present stood at 4,900, as compared with 4,674 at the corresponding date in 1939. Reference was made to the setting up by the Branch Council of two Protection of Practices Committees—one for London and one for Middlesex—and to the service of many Division secretaries as secretaries of the Local Medical War Committees.

Mr. Moore, as one of the representatives of the Branch on the Central Council, reviewed the Council's work during the war. The loss sustained by the Association and the Branch in the death of Dr. G. C. Anderson was grievous, and the recollection of the man and his work was still fresh in their minds. His successor, Dr. Charles Hill, had proved himself most valuable to the Association and to the profession at this critical time. The work of the Council might be said to have been divided into two parts—the routine business of committees, and the work in connexion with the projected National Health Service, both before and since the introduction of the Bill. He added that he and the three other members who had recently been elected to the Central Council by the Branch had had no opportunity, in the absence of a contest, of putting forward their own position, but he desired to say on behalf of all of them that they stood firmly behind the decisions arrived at at the recent Special Representative Meeting.

The election of officers then took place. The only nomination for President-elect was Dr. E. A. Gregg. Dr. R. W. Cockshut, Dr. Humphrey Nockolds, Mr. Eric Steeler, and Dr. H. H. D. Sutherland were elected Vice-Presidents; Dr. Alastair French was elected treasurer, and Dr. C. G. Martin honorary secretary, all of them unanimously. A vote of thanks was accorded to the retiring officers, including Sir Crisp English, the President, and Dr. L. G. Glover, who had acted as treasurer during the war while Dr. Alastair French was away on service, and also to Miss Wood, the clerk of the Branch Council.

Legal Problems in Obstetrical Practice

Dame Louise McIlroy was then installed as President of the Branch, and gave an informal address from the chair, discussing some legal problems in obstetrical and gynaecological practice. She remarked on the ignorance of the law often displayed by doctors. Whenever it was suggested that there should be special instruction in this subject the objection was raised that the curriculum was too full already. It would be a very great advantage to have, in connexion with, say, the University of London, a medico-legal institute, a centre for teaching graduates both in medicine and in law. The territory of the two professions adjoined, and it was not easy to say where the one ended and the other began. Graduates in law commonly knew as little of medicine as graduates in medicine knew of law. Many doctors made mistakes, especially at the beginning of practice, which were solely due to ignorance of legal requirements and procedure. For example, they had

never been instructed in the proper way of giving evidence in court. The inexperienced medical witness was generally inclined to talk too much and to give his own opinions rather than the facts which the court was seeking. The consequence of talking too much in the witness-box was a liability to self-contradiction, of which a cross-examining counsel was quick to take advantage.

She went on to discuss various questions in the field of obstetrics which were likely to come into the courts. One of these was infanticide. The proof of live birth was still a controversial point. In large cities, of course, an expert pathologist was generally available, but elsewhere the young general practitioner might find himself having to carry out the post-mortem examination of an infant. To determine whether the crime of infanticide had been committed was by no means easy, for injuries observed on an infant might well have been the result of difficult labour. After an extensive study of the literature she was convinced that there was no very definite test as to live birth. The law was sympathetic to the woman who, in a state of disturbed mind, had destroyed her child. The conception of puerperal insanity was giving place to something wider, perhaps an exhaustion psychosis.

One of the most difficult things even for the specialist was the diagnosis of pregnancy, and as for the general practitioner he, like the specialist also on occasion, was often a very unsuspecting individual and likely to take the word of the patient, accepting her story that she had missed certain periods and perhaps giving her a certificate stating that she was pregnant, of which she might make unscrupulous use. The diagnosis of pregnancy was less difficult when the Ascheim-Zondek test was available, and x-ray examination cleared up any doubt; but every precaution should be taken, especially in country districts where it was impossible to perform the usual tests. A great deal was to be gained by waiting; there was no need to rush to a decision in these cases. To determine the duration of pregnancy, which was often important from the legal point of view, was also difficult. If it could legitimately be done, in the case of a recently married couple, it seemed desirable to suggest prematurity of the infant rather than to cast a stigma. The determination of post-maturity also gave rise to difficulties, though here the radiologist could nearly always tell whether the child was post-mature.

As to paternity, what possible means were there of proving that a certain man was the father of the child? Blood-grouping was not of much use. The supposed father might refuse to have his blood examined, and the mother could refuse to have her blood grouped. On the debated question of sterilization of the woman, it was enough, in strict law, to have her consent, but it had to be remembered that the operation was denying to the husband the possibility of having more children, and it was always advisable to secure the husband's consent in writing, though legally this might not be necessary. Dame Louise McIlroy also mentioned the difficulty of giving an opinion in nullity suits. The appearance of the hymen might not furnish conclusive evidence of loss of virginity; it might be due to previous vaginal examination, the use of douching, or the placing of tampons in the vagina at menstruation.

Finally, she spoke of the need for maintaining strict confidence as between doctor and patient. If the patient did not desire her doctor to say what was the matter with her, no court of law should be able to extract it from the doctor. It was always most important to secure the consent of the patient both to examination and to the making of a report. It was sometimes difficult, when the husband was paying the fee and was naturally expecting to be told what was the matter with his wife; all that could be done in such cases was to give the report to the woman and to advise her to tell her husband.

British Medical Association

ANNUAL REPRESENTATIVE MEETING, 1946

The Annual Representative Meeting of the British Medical Association will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Tuesday, July 23, and succeeding days.

RESOLUTIONS BY DIVISIONS AND BRANCHES

PRELIMINARY

A Charter for Health

Amendment by PLYMOUTH: That the publication entitled *Charter for Health* should be subsidized by the B.M.A. and sold to the public at a considerably reduced price.

National Health Service Bill

Motion by DORSET: That in the opinion of this meeting, if the British Medical Association recommends the profession not to accept service under the proposed National Health Service, the B.M.A. should also recommend doctors not to give any certificate to their patients which could enable them to claim sick pay.

Motion by SHEFFIELD: That in the opinion of this meeting it is essential that the Representative Body give a lead to the profession as a whole, on procedure for the conduct of practice in the event of the Health Service Bill in its present form becoming law.

HOSPITALS

"General Practitioner" Hospitals

Amendment by TROWBRIDGE: That this meeting views with concern the implications of paragraph 15 of Appendix I of the Council's Report; and urges the Council to modify the policy therein outlined, and to assist rather than discourage the further development of general practitioner hospitals in small provincial towns.

Amendment by MID-CHESHIRE: That the severe limitations in scope suggested for the general practitioner hospitals be not approved as these smaller hospitals are the backbone of the practice of medicine and surgery in rural and semi-rural areas.

Amendment by REIGATE: That the Report on "General Practitioner" Hospitals be approved provided that no measure be taken to limit the freedom of judgment and action of a practitioner. A practitioner must not be prevented from carrying out such work as he is capable of efficiently performing provided that he fulfils standards required under the present N.H.I.

Motion by PADDINGTON: That this meeting welcomes the Minister's sympathetic attitude towards closer co-operation between the general practitioners and the hospitals.

Motion by WORCESTER AND BROMSGROVE: That this Representative Meeting commends the Council on its report on general practitioner hospitals and trusts that this will be kept much in mind and believes that any administrative difficulties will be overcome.

Chronic Sick

Motion by PLYMOUTH: That in the opinion of this meeting the problem of caring for the chronic sick would be appreciably minimized if more active steps were taken to attract women to nursing and work of a domestic nature.

Motion by WILLESDEN: That this meeting is of opinion that inadequate provision is at present made for the treatment and care of the elderly and/or infirm, and instructs Council to set up a committee to investigate the whole position and report.

Motion by WORCESTER AND BROMSGROVE: That this meeting considers that special provision should be made for the care of the elderly and infirm who are unable to receive attention in their homes and who do not require hospital treatment.

GENERAL PRACTICE

Fees for Life Insurance Examinations

Amendment by PLYMOUTH: That until the term "Modified Examination" is defined, this meeting does not agree to a modified fee for Life Insurance Examinations.

Private Practice under 100% National Health Service

(Para. 30 of Annual Report)

Amendment by WORCESTER AND BROMSGROVE: That sub-section 2 be approved, subject to the ethical rules of the profession.

Amendment by LIVERPOOL: That sub-section 4 be amended by the deletion of the words "except in an emergency."

Amendment by WORCESTER AND BROMSGROVE: That sub-section be amended (a) by the insertion of the words "or while the patient is temporarily resident away from home" after the words "exec in an emergency," (b) by the substitution of the words "as agreed with the local executive council" for the words "as agreed by the local executive council."

Amendment by LIVERPOOL: That sub-section 5 be amended by the substitution of the words "two weeks" for the words "as short as possible."

Amendment by LIVERPOOL: That sub-section 6 be deleted.

Para. 30 of Annual Report is as follows:

1. That the principle of collective responsibility obtaining under the present N.H.I. scheme should not hold in the new service.

2. A general practitioner who contracts to give service under the National Health Service should be entitled as a right to accept patients as private patients. He should be entitled to treat private any person who is not on his own list or that of any partner, assistant, whether on the list of another doctor or not. Where a practitioner has accepted a patient as a public service patient he shall be precluded from charging fees for any service he renders that patient as a general practitioner.

3. A practitioner should be free to give such certificates, prescriptions, orders, or reports to his private patients as would secure for them any of the statutory benefits under the National Health Service.

4. Except in an emergency a general practitioner should not be required to treat as a public service patient any person: (a) not on his list; (b) who resides outside the area of his practice (as agreed by the local executive council).

5. A general practitioner should have the right to refuse to accept any person as a public service patient without giving reason. Similarly, a patient should have the right, without giving reasons, to ask for the withdrawal of his name from a practitioner's list. A general practitioner should be entitled to ask for the removal of a patient from his list without giving reasons, but he should give notice of his intention to do so to the patient, and the patient should be allowed to continue treatment for a limited period until the patient is accepted by or is allocated to another practitioner. The interval for change of doctor (other than by consent) should be as short as possible.

6. Where a public service patient on a doctor's list desires to be treated privately by that doctor, the patient should be required to give notice of his intention to do so to the doctor, and the doctor should be required to give due notice of the withdrawal of his name from the doctor's list.

7. A member of a partnership who elects to remain outside the service should not treat as a private patient any patient on the list of another partner in the firm. He should be regarded as a deputy in these circumstances; but this should not preclude him from treating as private patients those seeking his advice as a consultant specialist.

8. Public general practice should be held to mean the treatment by the practitioner of persons on his list at the place appointed for the purpose—i.e., the health centre, the doctor's surgery, or the patient's home—but where public practice is conducted from the health centre private practice should be conducted at some place other than the health centre.

9. A patient should not be required to give official notification of his intention to obtain his general practitioner service privately. The doctor may obtain for his own use such evidence as he thinks desirable.

Motion by REIGATE: That, in agreement with the decisions reached at the S.R.M. in May, 1946, this meeting considers that it is essential that the financial and administrative arrangements should be such that neither doctor nor patient is penalized if he chooses to remain outside the service.

Motion by KENSINGTON: That Council be requested to give urgent consideration to the methods by which private practice may be maintained in the future.

Supplementary Clothing Coupons

Amendment by HARROW: That the Council be instructed to press the Board of Trade to take such action as will improve the supply of operating gowns, surgeons' coats and overalls, so that an issue of supplementary clothing coupons can be made with which to obtain these articles.

Amendment by WORCESTER AND BROMSGROVE: That this meeting urges the Council to press further for a supply of supplementary clothing coupons for surgeons' gowns.

Admiralty Surgeons and Agents

Motion by SOUTH ESSEX: That the Council be asked to take action in order that the scale of fees paid to Admiralty Surgeons and Agents be revised in order to conform with the revised fees now paid by the Service Departments to civilian medical practitioners in accordance with para. 42 of Council's Report.

NATIONAL HEALTH INSURANCE

Report of Spens Committee

Motion by DARLINGTON: That, in view of the findings of the Inter-Departmental Committee on Remuneration of General Practitioners, and particularly in the light of its findings as evidenced

Para. 19 of the Committee's report, and the reinforcement of these findings in Sir Ernest Fass's rider to the Report—para. 4 of the rider—this meeting is of opinion that the consideration of an appropriate capitation fee since 1939 should be considered "from the ground up"; that this should be done immediately; and instructs Council to proceed with negotiations with the Ministry of Health on the matter with all speed.

Motion by PADDINGTON: That this meeting regrets that in spite of the general raising of salaries and remuneration in the community, the remuneration of insurance practitioners has so far been increased from 9s. to 10s. 6d. only.

SPECIAL PRACTICE

Consultants and Specialists and a National Health Service

Amendment by HARROW: That the following words be added to the section (iii): "unless the consultant himself wishes to call in another consultant from outside the district."

Subsection (iii) of para. 52 is as follows:

Consultants should be available under the scheme for domiciliary work only within the district they serve.

Examination of Pensioners referred to Specialists

Amendment by LANCASTER: That the first paragraph be referred back to Council for further consideration.

ORGANIZATION

Subsistence Allowance of Representatives

Motion by OLDHAM: That the Representative Meeting requests the Council to consider again the question of payment of expenses on a standard scale (for example, the Whitley Council scale) to representatives when attending a Representative Meeting.

PUBLIC HEALTH

Salaries in the Public Health Service

Amendment by SHEFFIELD: That this meeting expresses dissatisfaction with the result of negotiations on the interim revision of the Askwith Scale and considers that the lives upon which these negotiations were conducted should not serve as a precedent for any future negotiations.

BRITISH MEDICAL JOURNAL

Motion by PADDINGTON: That this meeting urges that the *British Medical Journal* should contain more authoritative regular articles on "Recent Advances and Treatment of Diseases" for the general benefit of practitioners.

OTHER MOTIONS

Study Groups

Motion by EAST HERTS: That this meeting instructs the Council to advise every Division to establish, where not already in existence, one or more local study groups, in order to secure the wider discussion of medico-political problems, to ensure a more intimate sharing of views, and to attract the active co-operation of more medical men and women in the formation of policy.

Postgraduate Study

Motion by PADDINGTON: That this meeting wishes to emphasize the crying need of general practitioners for postgraduate study to keep abreast of the rapid advances in diagnosis and treatment; all the more so as the opportunities were few and far between during the war.

Alien Practitioners

Motion by SHEFFIELD: That alien medical practitioners who have served as such in the British or Allied Forces and who are now unable to return to their native country should be allowed to practise in the United Kingdom provided they conform with such regulations as may be required under the Medical Registration Acts.

The Nurses Bill (Northern Ireland), which has just been published, provides for a *Roll* of assistant nurses to be started and kept by the Joint Nursing and Midwives Council and for rules to be drawn up governing the training and experience necessary for admission to the *Roll*. There is to be an Assistant Nurses Committee of the Joint Nursing and Midwives Council. Any person using the title "nurse" who is not a registered or enrolled assistant nurse is subject to certain penalties, and no one may carry on an agency for supplying nurses without a licence from the Ministry of Health and Local Government.

Correspondence

N.H.I. Capitation Fee

SIR,—In the past attention has been drawn by letters in your *Journal* to the fact that the capitation fee paid under the National Health has not represented an economic return for services rendered, and that this service has in fact been subsidized by the private patient or by the private income of the doctor concerned. This view of the situation has now been confirmed by the Spens Committee, and the Winchester Division of the British Medical Association at its last meeting adopted the following resolutions:

This Division, having considered the Spens Report, notes:

(1) That the Spens Committee considered the capitation fee paid in 1939 to have been, and still to be, grossly inadequate; and (2) That National Insurance Medical Service has been subsidized by the private practice, and/or the private incomes of the general practitioners.

Arising from these observations the Winchester Division requests this meeting of the Representative Body to instruct the Council of the B.M.A.: (1) To demand an immediate increase of the N.H.I. capitation fee, with compensation to date back to the time when the B.M.A. first put forward its application for an increased rate. (2) To re-establish confidence in the integrity of the State in its contracts with the medical profession, to demand compensation from the State for its previous unilateral breach of contract whereby the income level of those to be eligible for medical benefit was raised arbitrarily, to the prejudice of the general practitioner already underpaid for his N.H.I. services. (3) That in any negotiations for capital repayment by the State regard must be had to the undervaluation of the goodwill due to this uneconomic N.H.I. capitation fee.

Our meeting felt very strongly that these points should be placed before the Government immediately, and it was hoped that other Divisions would give their vigorous support to them.—I am, etc.,

Winchester.

C. J. PENNY.

Feeding the Invalid by Permission

SIR,—Can you or your readers suggest a way of bringing home to the Ministry of Food that patients are not ill to a time-table; that a personal knowledge of patients is half the battle in treatment; and that the interpretation of rules by clerks who are not versed in medical matters is often a bar to the satisfactory treatment and progress of patients. The following cases will illustrate the situation.

1. A female infant suffering from coeliac disease was discharged from hospital on diet and advised to have a special issue of one egg, one banana, and 2 oz. liver per day, since she had been stabilized on these items in hospital. Four certificates and one statement of the case have been issued; the child is still without the special items after a fortnight.

2. A man of middle age had haematemesis during the night of June 4-5. The call to see him was received late in the morning of June 5. A food certificate was immediately issued and his wife instructed to take it to the food office the same afternoon, so that the patient might have available the necessary milk to commence diet when the time came. The wife reported that she could not have the milk supplied till the next week—and that with a long holiday week-end in between.

3. A boy aged 12 has been producing urinary calculi since the age of 3 months, and is so far as possible on a restricted calcium diet. An application was made for fruit juices to be made available for this case, action being taken in accordance with Med. 2, para 19. Application was made weeks ago: Maybe the Ministry has added it; anyway it has not reached yet.

Surely, Sir, the profession has not fallen into such disrepute that its certificates are not now recognized? One hears disturbing reports of the fate of foodstuffs sent to other countries: is it not time that we began to consider the needs of our own people?—I am, etc.,

Woolwich, S.E.18.

H. J. FENN.

Domestic Help for Doctors' Wives

SIR,—Thousands of doctors' wives—my own among them—have for some years past been putting up a gallant struggle, tied to the telephone and doorbell except when, as a pleasant change, they stand in queues while a very part-time woman "holds the

fort." Yet they manage, these unsung heroines, to keep smiling while looking after their children with one hand, doing the housework and often the bookkeeping of an unbusinesslike husband with the other, and even having an occasional baby. We ourselves start the day by getting in the sticks and coal (if any), cleaning the boots, looking to see what else has given way in the car, and performing many domestic chores for which a long and expensive education has so admirably fitted us; some of us have acquired a well-nigh perfect technique at the sink.

The question of "direction" to domestic service is, of course, a difficult one from the point of view of the employer and employee. From a Red Cross Hospital of which I was M.O. for three years but which had to close down for lack of domestic staff, in addition to the "would not works" who resented direction, we had to sack a prostitute, a convicted thief, a drunkard, and a Lesbian—an interesting criminological museum supplied by the Labour Exchange. That the Ministry of Health recognizes it is not entirely unconcerned is proved by the fact that various priority schemes have been evolved—on paper. Either the Ministry has not the influence necessary to co-ordinate these schemes with those of other Departments or it has just "folded up." In this particular area the two or three hard-pressed doctors' wives watch all available part-time domestic labour absorbed by an E.M.S. Hospital and a lunatic asylum. The scheme for importing domestic help from Ireland came to grief in our case because, although arrangements were complete, the immigration regulations were changed at the last minute. Now there is a new plan for importing Danish domestics for hospitals and doctors, but the Labour Exchange informs us that we have to know of a specific individual willing to come.

It is high time that the Ministry recognized the debt it owes to the G.P.'s wife for her share in enabling him to do the work (for which, at any rate in the case of panel patients, it has made itself responsible) with anything like efficiency during a difficult period. Let it therefore produce a scheme and get down to implementing it, to the relief of these overworked wives of ours. Until it does so my telephone and doorbell will not be attended whenever and for such periods as my wife wishes to be out on business or pleasure. Emergency panel calls and private, midwifery, or accident calls will be unheard, as in other doctors' houses also. When health centres are established in every village to which our telephones and waiting rooms are transferred, our wives will be able to lead an existence free from care. And they will have earned it—bless them.—I am, etc.,

Arlesey, Bedfordshire.

M. L. FARMER.

B.M.A. LIBRARY

The following books were added to the library during March and April, 1946:

- Annessa, G.: *Vita e Cancro*. Vol. I, Parts 1 and 2. 1945.
Baumgartner, J. G.: *Canned Foods: An Introduction to their Microbiology*. Second edition. 1946.
Beckman, H.: *Treatment in General Practice*. Fifth Edition. 1945.
Bicknell, F., and Prescott, F.: *The Vitamins in Medicine*. Second edition. 1946.
Blacker, C. P.: *Neurosis and Mental Health Services*. 1946.
Boppe, M.: *Traitement Orthopédique de la Paralyse Infantile*. 1944.
Brachet, J.: *Embryologie Chimique*. 1944.
Burbury, W. M., et al.: *An Introduction to Child Guidance*. 1946.
Cameron, A. T., and White, F. D.: *A Course in Practical Biochemistry for Students of Medicine*. Fifth edition. 1946.
Chamberlain, E. N.: *ABC of Medical Treatment*. 1946.

H.M. Forces Appointments

ARMY

- Major-Gen. G. Wilson, C.B., C.B.E., M.C., late R.A.M.C., has retired on retired pay.
Col. (now Major-Gen.) W. Foot, M.C., to be Acting Major-Gen. Col. (Acting Major-Gen.) R. W. Galloway, C.B., C.B.E., D.S.O., late R.A.M.C., to be Major-Gen.
Col. R. G. Shaw, O.B.E., M.C., late R.A.M.C., has retired on retired pay, and has been granted the honorary rank of Brig.
Lieut.-Col. D. H. Murray, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

- Major (War Subs. Lieut.-Col.) V. C. Verbi, O.B.E., and Major H. C. Benson to be Lieut.-Cols.
Short Service Commission.—War Subs. Major W. Thomson has relinquished his commission, and has been granted the honorary rank of Major.
Capt. C. D. Salmond has been placed on the Half-pay List on account of disability.
Short Service Commissions.—Capt. H. Foster, D. B. Watson, D. W. Moynagh, R. M. Vanreenan, and J. H. Brodie have been appointed to permanent commissions.
Lieut. (War Subs. Capt.) C. C. Petrovsky, from Emergency Commission, to be Lieut., and to be Capt.
L. H. Pimm to be Lieut.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

- War Subs. Lieut.-Col. C. Donald, O.B.E., has relinquished his commission on account of disability, and has been granted the honorary rank of Col.
War Subs. Majors A. Gould and H. N. Levitt have relinquished their commissions, and have been granted the honorary rank of Lieut.-Col.
Major D. E. Jones has resigned his commission.
War Subs. Capt. E. L. Carter, A. A. Alderice, and W. Edgeworth have relinquished their commissions, and have been granted the honorary rank of Major.

War Subs. Capt. G. A. Wray and J. A. P. Evans have relinquished their commissions on account of disability, and have been granted the honorary rank of Major.

War Subs. Capt. A. T. Rogers and J. M. Mervis have relinquished their commissions, and have been granted the honorary rank of Capt.

War Subs. Capt. A. M. B. Tompkin, I. Lipman, W. M. Rich, A. C. Price, and J. Scott have relinquished their commissions on account of disability, and have been granted the honorary rank of Capt.

War Subs. Capt. L. Tajkef and S. Konarski have relinquished their commissions.

War Subs. Capt. D. F. Mehta and M. E. Winters have relinquished their commissions on appointment to the I.M.S.

To be Lieuts.: N. H. Ashton, D. A. N. Barran, A. Batty-Shaw, F. Cullis, T. M. J. d'Offay, W. J. L. Francis, W. M. Fyfe, E. Gilderdale, M. J. T. Hewitson, K. P. Higgs, J. L. Kelly, P. F. Lucas, A. B. G. Laing, W. G. Merriman, J. A. Martinez, A. G. Melfrose, W. C. Menzies, J. L. McConchie, I. MacDonald, R. J. McIlroy, N. A. Punt, C. J. Radway, G. H. Rees, P. L. Rhodes, T. A. Richards, R. E. Riley, R. Saffley, A. T. Sandison, R. H. Sewell, A. A. Shein, J. Simpson, A. G. Stansfield, A. A. B. Swan, T. J. Thompson, W. M. Van Essen, L. Vogel, D. Wilkes, J. R. F. Williams, E. Wood, J. F. B. Wyper, N. H. Rutledge, P. E. Baldrey, A. R. Beaton, A. R. Buckley, A. F. Catto, J. M. Fabricius, N. R. Fenton, P. B. S. Fowler, A. St. F. Henley, G. L. G. Hine, T. W. Howat, A. W. R. Jenkins, N. G. Johnston, G. F. Jolly, G. D. Lees, R. Majdalany, M. Usiskin, J. M. Walshe, P. Watson, and W. Tausig.

WOMEN'S FORCES

EMPLOYED WITH R.A.M.C.

War Subs. Capt. (Mrs.) L. V. Rosenbloom, (Miss) M. M. Shepherd, (Miss) A. E. Anderson, (Miss) H. O'Hara, and (Miss) E. L. Peters have relinquished their commissions, and have been granted the honorary rank of Capt.

War Subs. Capt. (Miss) M. M. Stern and (Miss) O. Bernstein have relinquished their commissions.

Mrs. Clara Lee and Miss Viola E. Shafto to be Lieuts.

ROYAL AIR FORCE

Gp. Capt. W. G. L. Wambeck has retired and is re-employed. Squad. Ldr. (Temp. Wing Cmdr.) J. H. Cullinan has reverted to the Retired List, retaining the rank of Wing Cmdr.

Squad. Ldrs. (Temp.) R. McP. Cross and H. W. Whittingham to be War Subs. Squad. Ldrs.

J. P. Sewell to be Fl. Lieut. (Permanent).

Flying Officer H. A. N. Hamersley to be War Subs. Fl. Lieut.

ROYAL AIR FORCE VOLUNTEER RESERVE

Fl. Lieut. (Temp. Squad. Ldr.) C. L. Clinton-Thomas has resigned his commission, retaining the rank of Wing Cmdr.

Fl. Lieut. (Temp. Squad. Ldr.) O. H. Sennett has resigned his commission, retaining the rank of Squad. Ldr.

Fl. Lieuts. (Temp. Squad. Ldrs.) W. Mirkin and K. C. Donovan have relinquished their commissions on account of medical unfitness for Air Force service, retaining the rank of Squad. Ldr.

To be Squad. Ldrs. (Emergency): N. W. Nisbett, D. Barton, V. H. Bowers, D. P. V. Meurs, R. A. Piachaud, W. T. H. Waies, W. McKechie, and W. M. Martin.

Fl. Lieuts. C. R. Naish, H. A. Wilson, and G. I. Davies have relinquished their commissions on account of medical unfitness for Air Force service, retaining their rank.

Fl. Lieut. P. R. Henson has relinquished his commission on reversion to the Southern Rhodesian Forces.

Flying Officers C. M. Shafto, R. W. Barter, L. N. Cook, B. V. Earle, W. A. Eggeling, G. W. Garland, F. G. Grant, R. K. Hay, D. T. Kay, M. S. Miller, W. A. Robson, H. O. C. Gammeltoft, W. L. Burrows, V. Altmann, A. Brown, D. W. R. Lyle, J. D. G. Turner, and A. B. Sclare to be War Subs. Fl. Lieuts.

To be Fl. Lieuts. (Emergency): T. A. Copp, K. G. Cumming, K. A. Butler, B. R. Little, M. G. Marks, St. J. G. O'Connell, G. R. Fisk, D. O. Williams, T. A. Grimson, H. Buckley, I. M. Hill, A. M. Howard, H. E. Vickers, R. F. Welch, and S. E. McConnell.

Flying Officer M. L. Van Baden has relinquished his commission.

To be Flying Officers (Emergency): A. A. Cohen, M. Evans, I. H. Foy, W. Hamilton, J. T. Hutchison, D. Leigh, D. Macleod, A. R. Makey, J. Rubin, P. H. Thomas, P. West, T. A. Evershed, J. J. Flemminger, D. P. Greaves, B. A. J. C. Gregory, D. G. Jones, W. K. Jones, B. H. McCracken, N. B. Malleson, S. H. Manners, J. H. Murphy, P. R. Ormrod, I. A. Porter, T. M. Roulston, W. Nick. Sandeman, G. H. Seale, D. W. S. Sheldon, J. R. Anderson, M. M. Andrew, G. M. Burns, A. Campbell, D. L. Davies, R. T. D. Esmond, P. Foster, J. Freedman, W. J. Jenkins, R. Just, G. McL. McGillivray, T. P. Magee, I. H. Mercer, I. S. Mudie, W. J. W. Sharrard, L. Shuck, E. Silver, R. D. Simpson, C. J. W. Soutar, R. H. Stillman, J. B. Stirling, H. F. Sugden, H. D. Symon, J. M. Thomas, D. K. M. Toye, J. D. Willins, R. R. Wilson, R. Vereker, J. D. Abbott, W. C. Adam, E. M. Allen, J. A. Cameron, J. A. Chalmers, J. D. Chalmers, R. S. Crow, L. D. Davidson, P. S. Dearden, H. Debovitch, J. Edwards, T. Ellis, D. Emslie-Smith, D. I. Ferguson, A. G. C. Findlater, J. K. Fleming, J. A. Gavin, C. Gething, H. S. Heddie, W. N. Kingsbury, J. R. McPherson, J. B. Maxfield, P. F. New, J. C. Reid, J. B. Russell, D. A. Sherman, T. J. Thomson, and W. S. T. Thomson.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flying Officers C. P. Cathcart, M. K. Keech, and J. S. Deans to be War Subs. Fl. Lieuts.

THE INDIAN MEDICAL SERVICE

Lieut.-Col. A. N. Sharma to be Col.

Majors F. M. Collins and D. P. Lambert to be Lieut.-Cols.

EMERGENCY COMMISSIONS

Major E. G. Michelson has relinquished his commission on account of ill-health, and has been granted the honorary rank of Major.

Capt. P. N. Swift has relinquished his commission on account of ill-health and has been granted the honorary rank of Capt.

Association Notices

GROUP OF ANAESTHETISTS

Notice is hereby given of the formation by the Council of a Group of Anaesthetists, which shall be composed of all those members of the Association who are engaged predominantly in the practice of anaesthetics. Members of the Association who claim to conform to this definition, including those serving with H.M. Forces, are requested to complete and return the appended form to the Secretary, B.M.A. House, Tavistock Square, W.C.1. The first general meeting of the Group will be held at a date to be subsequently announced in the *Supplement*.

CHARLES HILL.

Secretary.

June 22, 1946.

BRITISH MEDICAL ASSOCIATION

GROUP OF ANAESTHETISTS

FORM OF APPLICATION FOR MEMBERSHIP

To the Secretary,
British Medical Association,
B.M.A. House, Tavistock Square,
London, W.C.1.

I wish to apply for membership of the Group of Anaesthetists. I am a member of the Association and am engaged predominantly in the practice of anaesthetics.

Middlemore Prize

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1947 to the author of the best essay on: "The Aetiology and Treatment of Chronic Iridocyclitis." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1946. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1947.

Diary of Central Meetings

JULY

11, Thurs. Journal Committee, 10 a.m.

Branch and Division Meetings to be Held

SOUTHERN BRANCH.—At Polygon Hotel, Southampton, Wednesday, July 24, 2.30 p.m., 70th annual general meeting. Address by Dr. J. D. Lendrum: Miniature Mass X Ray.

Meetings of Branches and Divisions

PLYMOUTH DIVISION

Dr. G. D. KERSLEY chose the subject of "Occupational Therapy and Rehabilitation" for his B.M.A. lecture to the Plymouth Division on March 23, when Mr. C. F. Mayne presided. Occupational therapy, he said, might be described as "the application of occupations, crafts, and trades for their therapeutic effect on the physically and mentally unwell," while the word rehabilitation denoted

the complete process of treatment and training necessary to make the disabled fit to be of the utmost service to the community. As far back as the 2nd century A.D. Galen maintained that occupation was Nature's best physician, but this maxim was adopted only as a vague principle and only by the very wise until the later stages of the 1914-18 war. Good progress was made then, but afterwards little general interest was taken in the subject until 1940, though in 1936 the British Association of Occupational Therapy was founded. In 1940 the Army started a school for occupational therapy at Taunton, and later the E.M.S. asked the Dorset House School, then just moved from Bristol to Bromsgrove, to take over the training of technicians for its service.

Describing the establishment of an occupational therapy service in the Army, Dr. Kersley said that over-seas the diversional value was much greater than in this country, because of need for fostering morale in the convalescent who could not go on sick leave. Staffing had been possible only at hospitals with orthopaedic or psychiatric centres and at the convalescent depots. Here masseurs, and later masseuses, trained in occupational therapy at Taunton were employed, but at all hospitals there were diversional occupation centres staffed by sisters and nursing orderlies who had been trained in crafts at schools set up for the purpose in Egypt and Palestine. Treatment was prescribed by the physician in charge of the case on a special form providing space for diagnosis and indications and contra-indications, and the patient's capabilities and wishes were translated by the occupational therapist into a craft, a particular project and the tools being selected with a view to fulfilling the wishes of the doctor and at the same time gaining the patient's co-operation. At the hospitals soft toy-making, leather work, and embroidery were very popular, while at the convalescent depots and special centres the occupations were carpentry, metal and leather work. Improvisation and use of salvage were the order of the day; for instance, at one depot the whole lighting system was made by the occupational therapy department from parts of captured enemy vehicles. The department, once started, should be almost self-supporting, because the patient, if he wished to retain the article he had made, usually paid the cost price of the materials plus 10% for wastage, and other articles were sold.

Occupational therapy, as compared with remedial gymnastics, had the advantage that the exercise was carried out in a natural way, was spread over a longer period with the minimum of that fatigue engendered by boredom, and at the same time concentration on the disability was avoided. Moreover, it might be used to assess the patient's readiness to return to his normal duties. Co-ordination between occupational therapy, re-vocational training, and sheltered workshops and settlements had been attempted at the Ministry of Labour's Rehabilitation centre at Egham where, during the final stages of treatment, the patient was observed in the workshops, to decide what occupation he was mentally and physically capable of after discharge or the Government Training Centre to which he should be sent. If occupational therapy was used in its broadest sense and carried to its natural conclusion in this way, concluded Dr. Kersley, it might act as a link, helping to hold together the whole rehabilitation programme.

ABERDEEN DIVISION

"Population" was the subject of a B.M.A. lecture given by Mr. RICHARD TITMUSSE to the Aberdeen Division in the Medico-Chirurgical Hall, Aberdeen, on April 9. He said that 100 years ago one in every five confinements was an eighth or subsequent pregnancy; in a London Hospital in 1939 over 5% of the cases were first pregnancies and only 2% were eighth or subsequent pregnancies. This constituted a social revolution without precedent—i.e., in less than three generations sex had been completely separated from parenthood. It was the rate of change not only in fertility but in economics that created the crisis of modern society. Man had not diminished in procreative power—that is, the change was voluntary not involuntary.

The birth rate started to decline in the years 1873 to 1896 and continued to decline until the first World War. In 1919-20 there was a sharp rise, but in 1923—a significant year in fertility history—it fell below replacement rate—that is, one mother was not being replaced by a potential mother. In 1933 it reached its lowest level. After 1941 there was a rise to 1944, when a decline set in again. There was generally thought to be a big gap between the fertility rate of rich and poor. This gap was widest in 1911, when the fertility rate was 80% higher in the working class than in the professional and upper classes. The fall since 1911 was due to increased knowledge of contraception among the working classes; by 1930 the fertility rate among miners was lower than among mine owners and managers. This could explain the man-power shortage in the mines to-day.

During the war there had been no fall in the birth rate; this was probably due to the increase in marriages—an artificial inflation of the birth rate. In the same period there was no real increase in illegitimacy; before 1939 30% of first pregnancies followed pre-nuptial conceptions. There was, however, a remarkable decline

in third-plus births, and the fertility of women under 30 continued to decline throughout the war. A provisional analysis of the war years showed (1) fewer childless couples; (2) many fewer unmarried people of marriageable age; (3) no fundamental change in decline in the birth rate, which was below replacement rate, and there was a potential for a further fall.

Assuming the birth rate remained at its present level, the population in England and Wales within 30 years would have fallen by 2,000,000 and the number of people over 65 would have risen by 2,000,000. The working population between 15 and 64 would be smaller by 5,000,000.

For the next 50 years we were to see an ageing of the working classes. This was more important than any real reduction in numbers. The same was generally true, too, of Western Europe and the Dominions—that is, a problem of the white people.

In 1919 the population of U.S.S.R. represented half the population of Europe; by 2,000 A.D., if present fertility rate continued, it would be 5% more than the rest of Europe.

Concluding, Mr. Titmuss said that voluntary parenthood was an innovation which was transforming population problems. Western civilization was entering upon a new phase of social development in which replacement of numbers would depend upon the production of wanted children. When children were something like a compulsory levy on married couples it did not matter to society how great the difficulties of parenthood might be. These difficulties did not prevent children from being born, although they might be condemned to a short and wretched existence. To-day, to a growing extent, people had children because they wanted them, or not at all. All the difficulties, real or imaginary, all the fears, rational and senseless, which had always beset child-bearing and rearing, had to-day, because parenthood was voluntary, been converted into obstacles to child-bearing. This new freedom of parenthood marked the end of the epoch of automatic replacement of population. Henceforth replacement would depend upon the strength of the desire for children in the community and the extent to which that desire was not thwarted by adverse circumstances. This voluntary parenthood therefore obliged society to adopt a population policy which must recognize all the obstacles to parenthood and take action to remove them.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Experimental Medicine and Therapeutics.—Tues. 5.30 p.m. Annual general meeting: Election of Officers and Council for 1946-7. Short papers by Dr. J. H. Humphrey and Dr. H. J. Jones: Penicillin Inhalation for Pulmonary Infection; Dr. F. Avery Jones and Dr. J. H. Humphrey: Management and Biochemical Studies in Severe Oliguria following Abortion.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.—Tues. 5 p.m. Dr. R. T. Brain: Electro-therapeutics.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Mon. 8.30 p.m. Discussion on Nutrition to be introduced by Dr. Simon Yudkin and Prof. John Beattie.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tues. 5 p.m. Mitchell Lecture by Dr. P. M. D'Arcy Hart: The Search for Chemotherapeutic Agents in Human Tuberculosis during the Past 100 Years.

APPOINTMENTS

HILLIARD, L. T., M.B., B.Ch., D.P.M., Medical Superintendent, Fountain Hospital (L.C.C. Mental Health Services).

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BIBBINGS.—On June 17, 1946, at Woodhayes, Exeter, to Joyce (née Webb), wife of Ralph Bibbings, M.R.C.S., L.R.C.P., a daughter—Alison Mary.

MALCOMSON.—On June 23, 1946, at Staunton-on-Wye, Hereford, to Madeline, M.B., Ch.B., and E. W. Malcomson, M.B., Ch.B., a son—James Martin.

NISBET.—On June 22, 1946, at Twyford Nursing Home, Bognor Regis, to Mary (née Haile), wife of Squad. Ldr. N. W. Nisbet, F.R.C.S.Ed., a daughter—Lesley McGregor.

SMALLPEICE.—On June 25, 1946, at "Felcroft," Felbridge, East Grinstead, to Olive (née James), L.D.S., R.C.S., wife of John Smallpeice, M.R.C.S., L.R.C.P., a son.

MARRIAGE

WILLIAMS—PLIMPTON.—On June 24, 1946, John Llewelyn Williams, M.B., Ch.B., to Freda Joan Plimpton, both of Chirk.

DEATH

WILLIAMSON.—On June 27, 1946, at 2, Camp Terrace, North Shields, James Burtell Williamson, M.B., B.S., formerly Medical Superintendent of Preston Hospital, North Shields.

PROGRESS OF AVIATION MEDICINE IN THE ROYAL AIR FORCE AND ITS APPLICATION TO THE PROBLEMS OF CIVIL AVIATION*

BY

Sir HAROLD E. WHITTINGHAM, K.C.B., K.B.E., LL.D.Glasg., F.R.C.P., F.R.C.S.Ed.

Air Marshal, lately Director-General of Medical Services, Royal Air Force

In choosing a subject for this lecture in memory of the immortal William Harvey, physician and biologist, I feel that it would be appropriate, so far as the Royal Air Force is concerned, to give you a brief survey of the progress made in the physiology of aviation during the war and its application to the problems of civil aviation. Though aeronautics were unknown in Harvey's day, he was deeply interested in circulatory and respiratory phenomena, and these are much involved in certain important flying problems, particularly those of high acceleration and altitude. Harvey would have rejoiced to see how the experimental method has been applied to the biology of flying and would have marvelled at the progress made in this branch of medical science, also at the way that contemporaries and the public have accepted it and recognized its importance. Although Harvey discovered the circulation of the blood in arteries and veins, his conception of the circulation of the blood to the lungs was very wide of the mark: he thought that the inspired air cooled the blood and so prevented it from boiling at ground level. We know now that the blood actually boils at altitudes of over 60,000 ft. (18,280 metres) if compression is not employed.

Harvey applied the experimental method to gain knowledge for the benefit of humanity. I propose, therefore, to try to indicate to you some of the blessings to man that have accrued from aviation medicine researches in the Royal Air Force during the war and how many of these can be applied to the physiological and psychological problems of civil aviation.

Before the war the control of civil aviation, including licensing for civil flying, was vested in the Secretary of State for Air, and a special department existed at the Medical Headquarters in the Air Ministry to deal with the medical aspects, particularly the assessment of fitness to fly. After the outbreak of war this work still continued to be done by the Air Ministry, but on a diminished scale, as civilian flying was limited to testing and delivering aircraft and to manning a mere handful of passenger aircraft. Very little research in aviation medicine was done specifically on behalf of civilian flying, as practically all new developments were confined to Service types of aircraft. A few *ad hoc* problems were dealt with as they arose, and were common to civil and R.A.F. transport aircraft alike.

With the return of peace and the formation of a Ministry of Civil Aviation the relation of Service to civil aviation medicine has altered somewhat, the position being as follows.

Present Position of Medicine as Applied to Civil Aviation

The Ministry of Civil Aviation does not possess a medical branch of its own, but relies on the extensive knowledge and experience of aviation medicine available at the Air Ministry. A close liaison is maintained between the Ministry of Civil Aviation and the Air Ministry Medical Directorate, which continues to advise generally in this country on aviation medicine matters. The Ministry of Health, however, is responsible for the sanitary control of civilian aircraft and passengers

arriving at or leaving airfields in England or Wales: the Scottish Department of Health is similarly concerned in Scotland. The Royal Air Force Medical Branch has behind it the results of many years of experience and practical observations on medical aviation problems, and has a highly skilled staff of specialists to give appropriate advice and investigate problems as they arise. In addition, the valuable services of the Flying Personnel Research Committee† and its subcommittees are available to the Ministry of Civil Aviation. This committee reports direct to the Secretary of State for Air. It consists of a body of eminent scientists representing physiology, psychology, neuro-psychiatry, neurology, hearing, vision, and statistics; it advises on researches into the medical aspects of all matters affecting personnel which might conduce to safety and efficiency in flying, including problems associated with the scientific selection of flying personnel. The Director-General of Medical Services of the Royal Air Force is an *ex-officio* member of the committee. There are executive members of Air Staff representing operations, training, and research, a medical and an executive member for the Fleet Air Arm of the Navy, and a scientific officer (non-medical) of the Ministry of Civil Aviation. Other medical and non-medical individuals representing the practical interests involved are co-opted as required. The researches carried out under the aegis of this committee are done mainly at the Institute of Aviation Medicine at Farnborough, the Psychological Department of Cambridge University, and in the field by the Flying Personnel Medical Officers of the various flying Commands.

It would not be economical to duplicate these facilities purely to give civil aviation medical independence. Moreover, even if this were considered desirable, it would be some time before a new and separate staff of medical men could attain the knowledge necessary, unless either appropriate personnel were seconded from the Air Force or retired officers were employed. It would be an asset, however, if there were a Medical Adviser in the Ministry of Civil Aviation to make liaison with the medical authorities and scientists engaged in aviation medicine matters—civil, Service, and international—and to help keep the human factor in flying in proper perspective and abreast of progress of the machine. Otherwise there will be a tendency to revert to the pre-war attitude, when man's requirements were a secondary consideration to those of the aircraft. To obtain the best results the machine and its equipment must be designed and built to fit man.

I propose now to review a few of the more pressing problems of aviation medicine that confronted the Royal Air Force during the war. To enable aircrew to handle powerful aircraft of all types it was first necessary to learn how to select the best human material by physiological and psychological

† The composition of the committee is as follows: Sir Edward Mellanby (chairman), Prof. F. C. Bartlett (psychology), Dr. E. A. Carmichael (neurology), Mr. C. S. Hallpike (hearing), Prof. A. Bradford Hill (statistics), Dr. B. H. C. Matthews (physiology), Sir John Parsons (vision), Air Vice-Marshal Sir Charles Symonds (neuro-psychiatry), Surg. Capt. R. C. May (Fleet Air Arm), Air Cdre. T. McClurkin (Chief Executive Officer), and Air Marshal Sir Harold Whittingham (Director-General of Medical Services, R.A.F.).

* Harveian lecture delivered before the Harveian Society of London at the Royal College of Surgeons on May 27, 1946.

methods; then to buttress their natural attributes by providing mechanical aids to enable them to withstand the abnormal conditions encountered at higher altitudes, in all climates, by day and night, as well as in manoeuvres of combat involving high acceleration, and to ensure, so far as was possible, survival in emergency—that is, during and after bailing out, ditching, or crashing.

Selection

The general medical examination for fitness for flying, including special tests for cardiovascular stability and neuromuscular and respiratory efficiency, introduced in 1919 and called the "Flack Physical Efficiency Tests," has proved its value. This examination is devised to ensure that those who pass are alert in body and in mind and have accurate vision, good muscle tone, quick reaction time, and a good sense of balance. These tests do not predict the individual's aptitude to learn to fly; they do, however, materially aid in the assessment of general physical fitness to withstand the stress of flying.

During the war additional tests were introduced to select personnel for particular aircrew duties; the chief of these were used to help assess power of co-ordination, cardiovascular stability, tolerance for rarefied atmospheres, night visual capacity, and hearing efficiency in aircraft.

(i) *The sensorimotor test* was devised to judge deftness of hands and feet and co-ordination between the limbs, eyes, and ears. Extensive investigations have validated this apparatus as an effective means of picking out those individuals who would fail to learn to fly on account of poor co-ordination. Approximately 25% of those who fail to learn to fly do so because of being too heavy with their hands and feet, while the other 75% fail chiefly for temperamental reasons. Unfortunately, no satisfactory test for temperamental fitness for flying has proved valid as a sole arbiter in the selection of aircrew on entry, except in the case of severe predisposition to nervous breakdown.

(ii) *The cardiovascular stability test* is done with a tilt-table to detect those who have a low diastolic blood pressure which fails to rise on change from the horizontal to the vertical position, indicating instability for aerobatics.

(iii) *The high-altitude test* is carried out in a decompression chamber, where rarefied atmospheres are simulated up to 40,000 ft. (12,180 metres), or more if necessary, at the rate of climb of a modern aircraft. This test is used to eliminate those who are liable to suffer from decompression sickness or "bends," due to the nitrogen dissolved in the body fluids coming out of solution under greatly lowered atmospheric pressure more rapidly than it can be disposed of by the lungs. It has been found that about 25% of all aircrew tested suffer from "bends" when submitted to this standard test, whereas only 10% of young fit pilots so suffer.

(iv) *The rotating hexagon test*, intended to provide a visual task simulating that performed by a night fighter pilot, has proved to be only a rough guide to the assessment of night visual capacity, owing to uncontrollable factors which affect night vision in degrees varying with the individual. The test has therefore been used only to prevent grossly night-blind individuals from being allocated to night-flying duties: this means the elimination of about 3% of candidates for flying. As regards the remainder, it is considered that the best way to approach the problem is to give them night-vision training, to teach them how to look and to perceive, and to refer to an ophthalmologist for special examination, including a scotometry test, anyone whose night vision appears to be below normal during this training.

(v) *The hearing efficiency test* is performed with a gramophone audiometer, and is designed to measure ability to receive normal speech signals in both ears as transmitted through telephones in the presence of a background of intense aircraft engine noise. This was introduced because the whisper test at 20 ft. (6.1 metres) cannot be standardized, owing to variables such as the tester's voice and noise background. It is also uncertain whether the whisper test passes individuals who would be inefficient in hearing telecommunication messages in the presence of aircraft noise. In addition to the gramophone audiometer, a pure-tone audiometer is used to test pure-tone reception at 5 frequencies (4,000, 2,000, 1,000, 500, and 250 cycles per second in either ear) and at a subjective level of 20 decibels above the normal threshold. Candidates with a threshold hearing loss greater than 20 decibels at any of the frequencies are rejected. These are good tests, but have the defect of needing special apparatus which requires to be kept standardized.

The Royal Air Force, with its vast number of aircrew, opportunities for carefully controlled observations, and accurate personal records, has been in an ideal position to assess the value of various selection tests. Such Service experience has been

used in formulating suitable tests for the licensing of civilian pilots, of whom there are two classes. The private pilot must hold a Class A licence, and pilots and other members of air crew of public transport or those employed as test pilots must possess a Class B licence, which entails passing a higher medical standard. As civil flying necessitates air travel over many countries, an international standard of medical examination for fitness to fly has been laid down by agreement of the appropriate authorities of the various countries concerned. Until January, 1946, the authority for this was the International Convention for Aerial Navigation (ICAN), with its head office in Paris. Now it is the Provisional International Civil Aviation Organization (PICAO), with headquarters in Quebec. The standard medical examination set for Class B licences is in some respects even higher than that for R.A.F. aircrew, particularly as regards physical fitness and hearing; good physical fitness is essential to help ensure against the fatigue of long flights, and perfect hearing is very important in connexion with modern radio aids to navigation for blind flying at night and in fogs. All aircrew of civilian airlines must be up to the PICAO medical standards for their particular duties (pilot, wireless operator, engineer, etc.), though extra tests and safeguards may be introduced if any company thinks fit. When stratosphere liners become the vogue a decompression test, of the lines of that in use in the R.A.F., will doubtless be included in the routine tests laid down by PICAO, in case mechanical failure or explosive decompression did occur.

There are important branches of aviation other than aircrew that have benefited from the Flying Personnel Research Committee's researches into the problems of selection of personnel. For example, psychological tests were devised to select Fighter Controllers, whose duties included direction of fighters in interception tactics and on offensive sorties, also of patrols on convoy duty. These tests proved successful in picking candidates with the intellectual capacities required, and demonstrated a strong positive relationship between test scores and operational efficiency. The adoption of these tests resulted in a reduction in training wastage of Fighter Controllers. Somewhat similar methods were applied with success to Filterers, who co-ordinated information received from a number of radar stations simultaneously to help plot the position and movements of aircraft. The results of these investigations and a study of Service Air Traffic Control Officers proved of value in determining the standard of candidates to be selected for the very important job of Air Traffic Controller in civil aviation. The recommendations were made regarding the qualities required in a Control Officer, also regarding promising sources of recruitment and selection procedure. Recently these tests have been modified and added to with a view to selecting for civil aviation the best pilots for safe flying. Here two tests deserve mention—namely, the *controlled approach* (which is an extension of the Cambridge cockpit test), to pick out those who tend to under- or over-shoot in their landing approach, and the *grid location test* (in which small objects on a grid-scale have to be accurately located), to select those with deft touch, imperviousness to turbulence in face of delay and error, and the ability to learn the sequence of controlled movements rapidly.

The wide Service experience gained with the decompression test to assess fitness for high-altitude flying has also proved of value in helping to formulate instructions for employees engaged in testing pressure cabins on the ground in aircraft work: to exclude those not suited for such pressure changes, and to ensure a safe rate of pressure change for a normal individual. It has been recommended, therefore, that all intended employees on this work should be medically examined to exclude diseases of the alimentary, circulatory, or respiratory system, including upper respiratory tract infections; also that they should be instructed how to ventilate their middle ears during ascent and descent, and, where possible, should be given a decompression-chamber test. The rate of pressure increase should not be greater than 1/2 lb./sq. in. (0.035 kg./sq. cm.) per minute for inexperienced operatives, and gradually increased up to 2 or even 3 lb./sq. in. (0.14 kg.–0.21 kg./sq. cm.) as experience is gained; decrease in pressure can be at the rate of 5 lb./sq. in. (0.35 kg./sq. cm.) per minute for the healthy.

It is convenient now to consider the problems of high-altitude flying, particularly those of adequate oxygen supply, decompression sickness, and explosive decompression.

Altitude Flying

In this country at the outbreak of war neither those engaged in Service nor in civil flying were really oxygen-minded. Moreover, the continuous-flow system of oxygen supply then in use allowed two-thirds of the oxygen to go to waste. The Medical Branch was therefore faced with two urgent problems: first, to make every member of aircrew oxygen-minded, and, second, to devise an oxygen supply system and mask that could prevent oxygen waste, give the maximum of comfort to the user, and be reliable in the severest cold when sitting or moving about the aircraft or on baling out. To make aircrew oxygen-minded, demonstrations of the ill effects of oxygen at various altitudes and current rates of ascent and descent could be mulated. As regards improvement of oxygen supply, an economizer and mask were quickly designed and developed to prevent oxygen going to waste during expiration, and to be foolproof against stoppage of flow should the breathing of the wearer be minimal, as during shock or unconsciousness. His new system more than doubled the operational range of aircraft from the oxygen point of view.

Several improved types of mask were subsequently developed as the result of operational experience, so that the latest mask (Type H) is practically ideal, combining the qualities of comfort, smallness, lightness, and perfect fit even during strenuous aerobatics.

To assess the relative merits of oxygen masks and systems under various conditions an anoxia meter was designed and reduced to estimate the amount of oxygen in the blood for any length of time without puncture of an artery, as had to be done formerly. The apparatus is simply clamped lightly to the ear and the oxygen content of the blood is measured by means of two photo-electric cells.

This provision of good oxygen equipment was vain unless aircrews and passengers co-operated by using it to the greatest advantage. All aircrew and passengers therefore had to be instructed regarding the value of oxygen in maintaining normal erebration, vision, and hearing at altitudes over 10,000 ft. (3,045 metres), as well as its role in delaying the onset of fatigue and the ill effects of cold. In addition, a mask-leak ester was developed and introduced to check the fit of oxygen masks before all flights in which oxygen was likely to be used.

Other oxygen equipment developments were mobile decompression chambers for testing and instructional purposes, a plant for separating oxygen from the air during flight, a portable oxygen set (weighing 5½ lb. (2.38 kg.) and containing 10 minutes' supply of oxygen) to enable aircrew to move about away from their station at oxygen-requiring heights, and a very light bale-out oxygen bottle (weighing 3½ lb. (1.47 kg.) and containing 10 minutes' supply) fitted into the parachute pack as a stand-by for those who might have to bale out at altitudes above 30,000 ft. (9,140 metres): this emergency oxygen supply is permanently connected with the oxygen mask and can be turned on immediately by pulling a release handle on the side of the parachute pack.

These Air Force oxygen researches, developments, and experiences have been a boon to civil aviation, and have provided all the data required to fix the necessary rates of flow of oxygen at various altitudes for crew and passengers, including invalids. The new civil aviation mask for passengers was designed and developed at the R.A.F. Institute of Aviation Medicine, and it is a direct descendant of Type H, modified to meet civilian needs. It is extremely light (weighing only 1½ oz.: 42.5 g.), is a good fit (being made in four sizes), and is of aesthetic appearance: it had also to be of the cheapest possible construction compatible with proper function, as the policy is to make these masks an individual issue of the "throw away when finished with" type, owing to difficulty of sterilization. The portable oxygen set is being adopted for use by stewards and passengers to enable them to move about in aircraft at oxygen-requiring heights, also as a stand-by for invalids at even lower altitudes: in this case the bottle is slung over the arm of the passenger's seat. Some of the Service decompression chambers will probably be utilized in the near future by civil aviation organizations to train members of aircrew, especially with the advent of stratosphere flying.

Stratosphere flying at altitudes above 37,000 ft. (11,270 metres) brought two further problems—namely, how to prevent the occurrence of decompression sickness or "bends," and the best means of compressing the oxygen breathed so as to maintain the normal sea-level amount in the blood. The obvious answer to both was to supply the right amount of pressure. Exactly how this could best be done required much

FIG. 1.—Oxygen mask designed and developed at the R.A.F. Institute of Aviation Medicine for use in civil aviation.

research. First, pressure suits were developed, and it was in one of these, filled with oxygen under a pressure of 2½ lb. per sq. in. (0.176 kg. per sq. cm.) that Fl. Lieut. M. J. Adams in 1937 attained the altitude of 54,000 ft. (16,450 metres): such suits were clumsy to wear and greatly hampered movements, so they quickly fell into disuse. The next step was the development of pressurized cabins to give full freedom of movement with adequate comfort and warmth. Researches in pressure-cabin design were based on applying a pressure of 7½ lb. per sq. in. (0.51 kg. per sq. cm.), so that at an altitude of 44,000 ft. (13,200 metres) the pressure within the cabin would be equivalent to that of the atmosphere at 18,000 ft. (5,480 metres). The question arose of the effects of sudden decompression on the occupants if the cabin pressure were lost owing to mechanical failure or to puncture by shellfire or to a port blowing out. From the results of experiments on animals it was assumed that the sudden change of pressure from the equivalent of the atmospheric pressure at 18,000 ft. inside the cabin to that of 44,000 feet outside would cause such violent expansion of the lungs, stomach, and intestines that serious bodily damage or death would result. This was disproved in the Physiology Laboratory at Farnborough in 1942. The experiment has been repeated hundreds of times since, and it is quite clear that a fit man suffers little or no ill effects from such explosive decompression, provided that at the time of the explosion he is breathing oxygen, as he should be for an atmospheric pressure equivalent to that of an altitude of 18,000 feet.

These researches have provided the knowledge necessary for civilian pressurized aircraft for altitudes envisaged at present. In fact, the present aim is for an internal pressure of 6½ lb. per sq. in. (0.46 kg. per sq. cm.), so that at 20,000 ft. (6,100 metres) the cabin pressure would be equivalent to that of the

atmosphere at 8,000 ft. (2,400 metres), and oxygen would not normally be needed except to turn on in emergency.

While awaiting the production of pressurized-cabin aircraft it was necessary, in answer to the appearance of the German pressurized JU86, to devise some temporary measure to permit operations between 38,000 and 44,000 ft. (11,570 and 13,200 metres). A pressure breathing equipment was therefore developed in conjunction with the Royal Canadian Air Force. By this means positive pressure is applied to the lungs so that the total pressure in them is greater than that of the surrounding atmosphere. This is done by increasing the pressure in the mask while a counter-pressure is applied to the thoracic and abdominal walls to make expiration less of an effort. The equipment consists of a "Mae West waistcoat," which also serves as an oxygen reservoir. It maintains a continuous pressure of 1/4 lb./sq. in. (0.0175 kg./sq. cm.) to chest and abdomen: greater pressure cannot be applied in this localized manner without seriously impeding the return flow of blood to the heart. This device therefore has a ceiling of about 46,000 ft. (15,000 metres). It is reasonably comfortable to wear, was used during the last year of the war by photographic reconnaissance units, and proved to be a valuable interim measure.

Aircraft were not only attaining to higher and higher altitudes but were reaching greater and greater speeds, which kept ever to the fore the problems of the effects on man of high acceleration and deceleration.

Acceleration and Deceleration

During the war extensive researches were carried out on problems of acceleration and deceleration in relation to aerobatics, crash landings, ditchings, and baling out and ejection from aircraft.

As aerobatics play little part in ordinary civilian aviation only brief reference will be made to this problem. Blacking-out during a tight turn or loop at high centrifugal acceleration leads to momentary loss of control of the aircraft by the pilot, maybe during a critical manoeuvre. It was therefore necessary, during the early stages of the war, to introduce anti-measures without delay and with the minimum of interference with the pilot and the structure of the aircraft, as every man and every machine were needed in the air. Researches had already shown that blacking-out was due to the blood, under the force of high centrifugal acceleration, being drained to the lower part of the body, particularly the legs, so stopping the circulation of the blood to the eyes and brain, and that this usually occurred in the normal sitting position after exposure to a force of about 5 "g" for 4 seconds. It was found that abdominal belts alone did not prevent blacking-out, but interfered with the return of blood from the lower part of the body to the heart when the force of "g" was released, and so did more harm than good. The immediate answer to the problem was the introduction of the crouch position, which raised the individual's blacking-out threshold by about 2 "g": thus the average pilot can withstand up to 7 to 7½ "g" for 4 seconds, which was sufficient at that time. To achieve this crouch posture all that was necessary as regards structural alteration to aircraft was to raise the rudder-bar position 6 in. (15 cm.) by fitting a simple stirrup with a heel support to prevent the foot slipping during tight turns.

Further developments were hydrostatic and pneumatic anti-"g" garments designed to equalize automatically the internal pressure built up in the body fluids by the accelerating force, so preventing the blood from pooling in the lower part of the body. During the past three years great progress has been made, by close liaison between U.S.A. and British workers, in the development of a pneumatic suit of light type capable of being put on or taken off almost as easily as an ordinary pair of trousers. The latest suit weighs only 3 lb. (1.36 kg.), can be worn either as underclothing or over slacks, and can be put on within two minutes and taken off in half that time. These suits apply pressure as required by means of inflatable bladders to the lower abdomen, thighs, and calves, and so prevent pooling of blood in the lower half of the body. The air pressure is derived from a source within the aircraft, such as the instrument pump, and, by means of a regulating valve, is increased or decreased proportionately to the force of "g"

applied. The valve can be set to cut in at a predetermined force of "g," as it is uncomfortable to have the pressure functioning for low forces of "g," such as are encountered when flying in bumpy weather and while taking certain evasive action. This type of suit raises the threshold for blacking-out by at least 2 "g," and in addition, by ensuring good circulation of blood to the head, lessens fatigue and helps to maintain good reaction time even in long and arduous flights. It is unlikely, however, that such suits will be required by pilots of civil air lines, except possibly to prevent fatigue on very long journeys.

There are problems of linear acceleration, however, that are applicable to civil flying, particularly those connected with crash landings, ditchings, and baling out and ejection from aircraft.

Crash Landing.—In crash landings various injuries, lethal and otherwise, are apt to occur as the result of the body being carried forward with the momentum of the aircraft and striking against some hard object or bending on itself to such a degree as to cause a wedge fracture of the spine. The commonest injuries are fractures of the skull or simply bruises and lacerations of the scalp and face, and fractures of the bones of the lower limbs and of the spine. The wearing of a safety belt low down near the pelvis is unsatisfactory, as it allows of so much forward flexion that fracture is apt to occur in the dorso-lumbar region, with serious immediate and after results: whereas a safety harness which supports the shoulders allows only slight forward flexion of the spine, and if fracture does occur it is in the upper dorsal region and the prognosis is therefore more favourable. Compression fractures of the spine are not so common in aircraft crashes as in parachute descents.

During the past three years extensive study has been made of the forces which the human frame can withstand without injury or without injury sufficient to endanger human life, with the aim of collaborating with aircraft makers in the stressing of airframes and the design of safety devices to reduce crash injuries to the minimum. The extent of injury sustained during aircraft crashes depends on the magnitude of the force applied, the area and site over which the forces are spread, the duration of the forces, and the relative movement between supported and unsupported parts of the body. For example, if the skull receives the first impact the area of contact is usually small owing to the curve of the skull, so that the pressure per square inch is high. The skull is strong, but the deflector which it can withstand without fracture is small: if fractured, the chances of survival are much lower than for fractures of other bones. The mortality rate for fracture of the skull in flying accidents is 94%. If the back and buttocks receive the first impact the area of contact is much larger, and appreciable deformation of tissues may result. Injuries to aircrew and passengers during crashes can be reduced by supporting the body over as large an area as possible, and by preventing the skull from hitting unyielding objects of small size. A posture facing backwards therefore give better protection from serious injuries than one facing forwards: whether supported by harness or not. Harness gives relatively poor protection against injury, as the area of the body covered is small compared with support of the whole back by the seat. From the physiological aspect, the ideal posture during crashing or ditching, is to lie or crouch with arms and legs flexed, the back and head fully supported, facing towards the rear of the fuselage. These postures reduce the effects of vertical deceleration on the spine, and are the basis of crouch positions adopted with success in various types of R.A.F. aircraft. A new safety-type harness has recently been developed to withstand the stresses liable to occur under existing conditions. A survey is being made of the important aircraft types, including jet-propelled machines, to find the maximum forward deceleration which can be withstood, and the anchorages of seat are being reviewed. The immediate aim is to produce a safety harness and seat which will withstand 25 "g."

A simple protective measure for passenger aircraft would be to place all seats facing to the rear instead of to the front; then, in the event of a forced landing, the passengers should be instructed to lean back in a crouched position with the head pressed firmly against the soft back of the seat and protected by the hands clasped tightly round the back of the neck. Generally speaking, if passengers' view from an aircraft would not be materially affected by this back-facing arrangement of seats. A special safety cell has been designed for crashes, but to carry these would occupy valuable space and unnecessarily increase the pay-load, for the padded seats reversed as suggested functions as a safety-cell.

Baling Out and Parachute Descents.—A considerable amount of research has been done to assess the decelerating forces involved when parachutes open at various altitudes and speeds: the higher the altitude and speed the greater is this force. The decelerating force applied to the parachute harness attached to a man of about 10 st. (63.5 kg.) in weight, at the moment of opening of the canopy at altitudes up to 25,000 ft. (7,620 metres) is usually less than

25 "g," and the standard parachute with its rigging is capable of withstanding this degree of stress: the harness is stressed to withstand over 40 "g." This decelerating force acts for only a second or so—the greater the force the shorter the duration—so that blacking-out rarely occurs unless the parachutist is anoxic at the time, as well be may be. Experiments with dummy men fitted with accelerometers indicate that forces up to 30 "g" occur at altitudes of 35,000 to 40,000 ft. (10,660 to 12,180 metres) if the parachute is opened almost immediately after baling out. Such decelerating forces may seriously damage the parachute and its rigging. It is essential at these higher altitudes, therefore, for the user to allow the rate of fall to slow down to terminal velocity before pulling the rip-cord: this takes about 12 seconds.

It is convenient to consider here the danger of unconsciousness and even death from anoxia resulting from baling out in the stratosphere. Members of the staff of the R.A.F. Institute of Aviation Medicine took part in a number of experiments to find out how long a man could live at altitudes varying between 44,000 and 25,000 ft. (13,200 and 7,620 metres) during parachute descent, even though unconscious. These experiments were done in the laboratory, the subject being suspended in the air by the standard parachute harness. In this way, by simulating the atmospheric oxygen conditions from 40,000 ft. (12,180 metres) down by the use of nitrogen-air mixture, at the rate of descent of an open standard parachute, it was found that man could remain unconscious and yet live up to a period of 7½ minutes. This is not adequate to ensure a safe descent, as it would take 7½ minutes to reach 20,000 ft. (6,100 metres) if baling out took place at 35,000 ft. (10,660 metres). Moreover, the unconscious parachutist would become limp and the head would fall forward and so be liable to cause respiratory embarrassment; while the cold is intense (-55°C.) at these altitudes and would materially reduce the chances of survival. A quicker descent could be made by doing a delayed drop from 35,000 to 20,000 ft. (10,660 to 6,100 metres), which would take 1½ minutes; by this time the individual might be so anoxic as to fail to pull the rip-cord. For this reason the emergency bale-out oxygen set was introduced, and has added greatly to the confidence of those flying at higher altitudes.

An R.A.F. medical officer, an expert parachutist, was installed at the Airborne Forces establishment in this country when the training of air-borne troops was first taken seriously in 1941, and remained there throughout the war. His duties were to advise on parachuting from a medical aspect, and, for this purpose, to make liaison with the Army Airborne Forces and the R.A.F. Institute of Aviation Medicine. Researches he undertook show that liability to injury on landing by parachute varies with age, weight, force of wind, and type of terrain. Statistics revealed that injuries were more frequent in those over 25 years of age than in younger persons; that the injury rate rose rapidly in those over 12 st. (76.2 kg.) in weight; and that the stronger the wind the greater was the risk of injury from wrong stance on landing. The commonest parts to be injured during training jumps were the legs (64% of those injured) and the head (24% of cases). The incidence of injuries during training was initially 4% of jumps, but, subsequent to improved attachment of parachute harness and landing stance, as suggested by this parachutist medical officer, it was reduced to 0.5% of jumps. In addition, a considerable amount of research has been done with different kinds of parachute to ascertain the most foolproof type, as regards both certainty of opening and the minimizing of the final deceleration on touching down. For this purpose visits have been paid to the parachute-training establishments in the United States of America and in Canada, also in Germany.

Critical analysis of rates of survival after baling out from multi-seated aircraft has given valuable information regarding difficulties of escape, such as the angle of the aircraft, the force of "g" resulting from spinning, jamming of hatches, and temporary amnesia. The findings stress the necessity for aircraft to be designed so that all occupants can leave within two seconds of the order to abandon aircraft. In this connexion anthropometrical research has given valuable information to aircraft designers regarding the size and shape of exits necessary to prevent fouling or injury.

All this information is applicable to civil aviation, for, when stratosphere flying becomes a commonplace, passengers and crew will very likely have to be provided with parachutes for use in emergency even if it becomes possible in future to eject the cabin complete with occupants.

Ejection.—As the result of a fatality in January, 1944, when a pilot tried to escape from a jet-propelled aircraft which was out of control, it became evident that the force of the slipstream in aircraft of very high speed is so great that the unprotected human body cannot withstand it for more than a fraction of a second, else limbs are evulsed against the machine. The problems involved were whether quick ejection of the man plus his seat would avoid this evulsion, and whether man could withstand the high force of positive "g" necessary to eject him clear of the tail of the rapidly moving aircraft.

It was first necessary to ascertain what was the maximum force that can be applied vertically to the spine through the seat without

injuring the spinal column, spinal cord, skull, or brain. The Martin-Baker test rig, at an angle of 30° off the vertical, proved best for this purpose. It was found that a man could tolerate in this way up to 20 "g" for a period of a tenth of a second, provided he was well strapped in with safety harness and that there was an appropriate device to prevent his head flexing forcibly and

FIG. 2.—Diagram to show how a man, strapped down with safety harness and provided with a canvas hood device to activate explosive ejection as from an aircraft, can tolerate a force up to 20 "g" applied vertically through the spine for 1/10 second. (The Martin-Baker test rig.)

acutely as the force of "g" was applied. Unless the head is protected it will fall violently forward on the chest, owing to the centre of gravity of the head being in front of the line of thrust of the spine. Trials with dummies in aircraft have shown that it is necessary to arrange for a 40-ft. (12.2-metre) ejection, with an ejection stroke lasting for one-tenth of a second at between 15 and 25 "g" upwards through the seat. This is attained by means of an explosive charge under the seat; the charge is activated by the pilot pulling a roller-blind affair of heavy canvas over his head by means of two rubber handles. When the handles reach the level of the diaphragm the pull activates the cartridge, and the resulting ejection with its high force of "g" makes the bands pull the protecting hood tightly down over the head. In addition to holding the head in position to avoid injury, the hood is intended to protect the eyes and prevent the oxygen mask being torn off by the force of speed.

FIG. 3.—Ejection from aircraft in flight of a dummy man complete with seat as a result of a 40-ft.-per-second explosive charge. The parachute, which operates automatically, is just opening. (Crown copyright photograph of official test done on Oct. 5, 1945.)

It is envisaged that civilian flying in the near future will be in very fast aircraft travelling in the stratosphere, and that arrangements will have to be made for the whole cockpit or cabin to be ejected in emergency. The detached cabin will require to be fitted with suitable parachutes to land it intact or to retard its speed so that

occupants can escape individually by parachute in the usual way at a convenient altitude.

This leads to a consideration of aircraft accidents in general, their causes and prevention.

Aircraft Accidents

It has often been stated that flying accidents are due to human error in at least 80% of cases, but this statement has never been validated: it can be assumed, however, that the human factor plays a very large part in the majority of air accidents. It is of prime importance, therefore, to eliminate from flying duties those who are accident-prone and to provide aids to increase safety in the air, particularly for blind flying, landings, and take-offs.

With these aims in view, researches were instituted to devise tests to predict the accident-prone individual. It was conceded that heavy-handed and leaden-footed individuals, or those visually defective owing to eye-muscle imbalance or gross night-blindness, were accident-prone as regards flying, and they are eliminated by appropriate tests on entry, as already indicated. There still remain a large group who are labelled temperamentally unsuitable to fly, and many of these are accident-prone. Attempts to predict these individuals by psychiatric and psychological methods have been disappointing, except in the case of the Cambridge cockpit test. In researches with this test, pilots were set a relatively complicated task analogous to flying an aircraft, and many aspects of their performance were scored and rated. It was found that those who sustained accidents or became casualties on operations had obtained high error scores in the test, and had been predicted unfavourably. The incidence of non-fatal accidents was highest in those who, though they obtained normal scores, had been rated unfavourably in one or more aspects. The rating was intended to indicate the stability and skill of the individual when obliged to carry out, for a relatively long time, a task in which he was unable to achieve a high degree of accuracy. Stability under stress is regarded as a more important attribute in avoiding accidents than the ability to learn the skill of flying.

Investigations have shown that *fatigue* is conducive to flying accidents, and a considerable amount of research has been and is still being done to assess the relative importance of the many factors involved in flying fatigue and the best means of overcoming or mitigating them. There are various causes of fatigue in aviation, such as the stress of taking-off with heavily laden machines or landing under adverse conditions and at high speed; the mental anxiety of night flying or flying through fog; the discomfort of a cramped and confined position; the effect of noise on the auditory sense; loss of vitality as the result of exposure to cold; and oxygen lack to the body cells when the supply is inadequate. As the cumulative effect of even small irritations is a potent cause of fatigue, there has been a constant endeavour to improve the design and fitting of all flying equipment so as to give the greatest efficiency with the maximum of comfort.

Researches into measures to abate these fatigue-producing factors have resulted in improved radio apparatus and direction finders to simplify night and blind flying without straining the eyes; improved cockpit and instrument lay-out, including dial markings and the best position for all controls so as to obtain the maximum human efficiency with the least fatigue; proper design of seats from an anthropometrical and physiological aspect, to avoid cramping and to lessen vibration; sound-proofing of cockpits and cabins to minimize engine noise; air-conditioning of cabins to maintain an agreeable temperature in all climates and at all altitudes; and the provision of an adequate oxygen supply, including design of mask to give maximum efficiency and comfort. The results of all this work have been passed on for use by civil aviation, including designers of aircraft, and it is hoped that the various improvements suggested will materialize in the new civilian aircraft now under construction and development.

Fatigue in aircrew has been shown to be usually of the skill variety, and results mainly from prolonged repetition of highly skilled performance. The individual concerned is often unaware of his condition and tends to blame the flying instruments for his mistakes. Researches have proved that this inability to make mistakes when fatigued can be countered if the individual has been instructed that fatigue is a normal

sequence of long periods of concentrated mental or physical effort, and that his performance can be almost as effective as when fresh if he realizes he is open to errors and exercises special care, particularly towards the end of the task.

The "beam approach" may be cited as one example of aids to flying and the prevention of accidents in which medical research has played an important part. This is one of the blind-flying devices on which a pilot has to rely in homing at night or in bad day visibility—that is, at a time when he is fatigued and liable to make errors. In addition to the beam approach indicator, a pilot has ten instruments on his blind-flying panel which have to be read and their meaning fitted into one whole before he can make a safe landing under blind conditions. It is of the greatest importance, therefore, that all instruments should present their messages as simply and clearly as possible. The beam approach briefly consists of a radio beam which gives two types of clue to the pilot—one auditory, the other visual. At first these clues were wrongly presented. The auditory clue, which was Morse, did not use the letters that could be picked up with least error; and the visual clue, which consists of a small luminous plan of the aircraft and its relation to the beam, was confusing, as the pilot had to remember to reverse the signal for right and left turn when coming in to the airfield in the opposite direction to the normal approach. Pilots, especially when tired, found this confusing, and often made a wrong response which resulted in a landing accident. The logical visual presentation is that which necessitates the minimum of thought. As a result of these psychological researches, correct aural and visual clues were introduced. The application of this to civil aviation needs no stressing.

Intensive researches into the causes and prevention of flying accidents are being continued by the Air Ministry; every crash is thoroughly investigated. From a medical point of view, statistics are collected covering such data as the type of aircraft involved; estimated speed of impact; posture adopted by each occupant before the crash, whether standing, sitting, facing fore or aft; parts of the aircraft which caused injuries to occupants; sites and nature of injury in each case; and any precautions taken to prevent injury. Appropriate action is taken to correct any faults found either in the structure or design of aircraft or equipment, or in the crash position or the drill of the occupants. It is hoped that, as a result, the incidence of air accidents will become progressively less, and that in those that do occur the survival rate will be high.

Survival after Crashing or Baling Out

Researches in connexion with problems of survival after baling out or ditching in the sea have been carried out by members of the Institute of Aviation Medicine in European waters. Some of these problems were tackled and solved in conjunction with the Admiralty, such as the production of drinking-water from salt water, the provision of the best type of survival ration, and general measures to preserve life when cast away at sea.

The first problem tackled was the development, in 1942, of an *immersion suit* for pilots of aircraft in the catapult armed merchant ships operating with convoys in North Atlantic and Arctic waters. The catapulted aircraft could not land on these ships, and the pilots had to bale out into icy waters, so that a suit was needed to enable them to withstand the severe cold on immersion for at least half an hour before they could be picked up. A suit was produced that was comfortable at stand-by on the ship and yet watertight. Immersion trials of this garment were carried out in Icelandic waters by a member of the physiology team to enable it to be perfected. It was made of a light waterproof gaberdine which allows perspiration to take place through it, yet by virtue of its texture and the arrangement of its fibres holds back water applied to it in the form of rain or during immersion. This suit, modified to meet requirements, was adopted by the Fleet Air Arm. Following the success of this garment, a watertight suit was developed to protect crews of high-speed launches of the Air-Sea Rescue Service against wind and spray.

In 1945 a lighter, inflatable *suit to guard against exposure* was designed and developed for aircrew to don either just before baling out or ditching, should time permit, or after entering the dinghy. It is made of balloon fabric, has a double

lining for inflation purposes, and is quilted to loculate the air to ensure that there is always a layer of air even at points of pressure. It weighs only 2½ lb. (1.25 kg.), and rolls up to form a stole for the "Mae West." There is a short tube at the neck for inflation by the mouth, and a hood to complete the protection. Even if it is not put on until the dinghy is boarded, it will protect the wearer against further loss of body heat despite wet clothing underneath.

Researches were also carried out with various *life-saving jackets* to assess their efficiency to prevent an injured or unconscious man from drowning. For this purpose a member of the physiology team was kept continuously anaesthetized while immersed in a swimming-bath wearing various types of life-saving jackets in turn, the body being pulled face down from time to time to see if it would right itself. Artificial waves were created to imitate rough water. Though the R.A.F. "Mae West" kept the nose and mouth of the unconscious individual clear of the water, it was improved for use in rough seas by a 2-lb. (0.9-kg.) lift in the back. A new jacket was therefore designed incorporating this and other improvements.

The immersion suit and the "Mae West" life-saving jacket, which are light and easily stowed, will be welcomed by civil air lines, particularly now that land planes are replacing flying boats on most, if not all, cross-sea and ocean flights.

Some Flying Problems

Time does not permit of more than passing mention of many other problems tackled, and solved, to improve man's efficiency in flying, whether in a Service or a civil capacity—for instance:

- (i) The protection of vision against *sun and searchlight glare* by special glasses and other devices.
- (ii) Means of obtaining and maintaining the *maximum night visual acuity*, by pre-adapting with red goggles, and using red or ultra-violet lighting reduced to the minimum to illuminate instruments and maps.
- (iii) Improved design of *microphones* and *earphones* to increase acoustic reception and so lessen fatigue.
- (iv) Design and development of *flying helmets* to give perfect fit with comfort even when worn for hours.
- (v) Proof of the occurrence of *high-tone deafness* as the result of flying for 100 or more hours without ear protection in non-sound-proofed cabins.
- (vi) Means of preventing and treating acute *altic barotrauma* by x rays or gamma radiation.
- (vii) Study of the causes of *dental pain at altitude* and its prevention, by proper conservative dentistry, using cement of the correct pH and avoiding undue heat near the tooth pulp.
- (viii) Study of *air-sickness* and its prevention, and discriminating between true air-sickness and emotional tension.
- (ix) *Design of cockpits and seats* for comfort; removal of projections likely to cause injury; placing of all controls in the most favourable position. The problem is whether the controls most often used or those needed in emergency should have place of vantage.
- (x) Simplification of *instrument dials* for ease of reading; grouping of instruments so as to cause the minimum of error and fatigue.
- (xi) The *disinsectization of aircraft*, and the *control of mosquito breeding* by aerial spraying of D.D.T.
- (xii) The *cooling of aircraft* on the ground in hot climates and protection of those servicing aircraft.

It is evident from the foregoing that the majority of aviation medicine researches carried out on behalf of Service flying have a direct or indirect bearing on civil aviation problems. For this reason, when considering the establishment of the new Institute of Aviation Medicine at Farnborough, it was decided to design, equip, and staff it to meet the requirements of civil aviation as well as of those of the Services—Royal Air Force, Fleet Air Arm, and airborne troops. Throughout the war there has been the closest liaison in all this work not only between the Services but also with the Dominions and our Allies: their scientists have worked alongside ours in the Institute, and in some instances still continue to do so. No less important has been the liaison with aircraft designers and scientists on the material side. It was by this whole-hearted co-operation and fine team spirit that such excellent and rapid progress was made in aviation medicine during the war; it is sincerely hoped that this friendly collaboration will continue

in peace to ensure the fullest support for aviation in general so as to make it the safest, most comfortable, and quickest mode of travel.

This is a high-speed aerial review of the progress made in aviation medicine during the war, and, as in an aerial view, the ground covered is extensive but detail is lacking: you get only glimpses of this new country through the clouds of obscure description and so your imagination must fill the gaps. Likewise, as you cannot see the whole world in an hour, even in the fastest of aircraft, so this picture of aviation medicine covers only a small portion of the valuable work done by as fine a team of scientists and medical officers as anyone has ever been privileged to direct.

I wish to pay high tribute to all those who have given so much and often risked so much in these researches—physiologists, psychologists, Flying Personnel Medical Officers, and Squadron Medical Officers, and to those who gave all—Group Captain Hugh Corner and Squadron Leader D. A. H. Robson.

INADEQUATE FEEDING IN HOSPITALS

A STUDY OF CONTRIBUTORY FACTORS*

BY

J. A. F. STEVENSON, M.D. McGill

Loss of weight, which is sometimes considerable, is not an uncommon occurrence in patients admitted to hospital. In Royal Canadian Army Medical Corps hospitals in Canada losses of weight have been noted in over half the patients observed, and ranged from 10 to 60 lb. (4.53–27.2 kg.).^{1,2} Lyons³ has reported similar losses of weight in soldiers in U.S. Army hospitals. Such findings are certainly not confined to those treated in military establishments, for Elman,⁴ Taylor,⁵ and others have recorded similar observations in civilian hospital patients. At the end of 1943 this state of affairs in Canadian military hospitals in Canada was surprising, since the raw food-stuffs available for hospital use were, according to accepted standards, and practices, more than ample.

In this paper, therefore, we record measurements made on actual food intakes of patients in Canadian military hospitals in Canada, and we report observations made during the past few years on factors which have contributed to inadequate protein and caloric intakes. We will also discuss briefly the relationship of so-called "toxic destruction" of protein to loss of body mass and to protein and caloric requirements. Finally, we will present some data to illustrate the effects of a campaign planned to maintain high standards of nutrition in the sick.

Methods

Dietary histories were taken and measurements were made of the food consumed by patients in Army hospitals in Canada. These men were subsisting on the ordinary ("full") hospital diet; they had normal gastro-intestinal tracts and were convalescent after surgical procedures. Over a three-day period all food actually offered to each patient was weighed before and after the meal. Hospital supplementary feedings were measured, and all patients kept a list of extra food supplied by friends or obtained from the Red Cross or the hospital canteen. Food platters were chosen at random so that the servings would represent those usually given by the nursing sister. The caloric, protein, fat, and carbohydrate values of the ingested food were calculated from National Research Council tables of food composition. The results were analysed statistically.

Various aspects of hospital catering which might affect intake of food were studied in over 30 hospitals. Observations were made on supplies of food available in depots, the ordering of

* From the Research and Development Division, Directorate General of Medical Services, Canadian Army, Ottawa.

food, kitchen and ward equipment, the ability and training of cooks, methods of cooking and serving food, and the attitude of the medical staff, the nursing staff, and the patients themselves toward food intakes.

Results

The ration scale for R.C.A.M.C. hospitals in Canada from which ordinary or "full" diets are prepared consists of 156 g. of protein, 144 g. of fat, and 539 g. of carbohydrate, and provides approximately 4,100 calories. From these sources the patient got three meals a day and sometimes supplementary feedings such as egg-nogs (100 to 200 calories and 10 to 20 g. of protein), milk, cocoa, and biscuits.

We found three main reasons why patients did not ingest their full ration. First, although foodstuffs were plentiful in depots, hospital staffs did not indent for their full entitlement; secondly, some wastage occurred during preparation of the food in the kitchen and through failure to use food left over; thirdly, considerable amounts of food were left on the plates by the patients. Improvement in food intakes which was noted some months after an educational campaign was instituted is here shown in a graph.

Graph showing the daily intake and wastage of calories and protein of patients in a Canadian military hospital before (white) and after (black) an educational campaign planned to improve hospital nutrition.

The results of the observations have been recorded for two hospitals in the accompanying Table. The average quantity of

Table showing the Total Intake of Protein, Fat, Carbohydrate, and Calories of each Patient each Day in Two R.C.A.M.C. Hospitals in Canada. The Amounts of Food Left on each Plate are also shown

Per Man Per Day	Proteins in Grammes		Fat in Grammes		Carbohydrate in Grammes		Calories	
	Hosp. A	Hosp. B	Hosp. A	Hosp. B	Hosp. A	Hosp. B	Hosp. A	Hosp. B
Food actually ingested	54	74	73	93	239	276	1,856	2,272
Food left on plate	21	12	22	11	119	69	772	428
Food served to patient	75	86	95	104	358	345	2,628	2,700
Food never obtained and kitchen wastage	102	70	71	40	300	194	2,279	1,435

food ingested by each patient each day, from hospital sources, provided 74 g. of protein and 2,210 calories. The lowest intake for each day of the three-day period was 25 g. protein and 764 calories, and six patients had less than 1,600 calories a day.

The highest intake in any individual was 114 g. protein and 3,094 calories. In one hospital in Canada the patients average only 54 g. of protein and 1,856 calories.

Factors Contributing to Hospital Malnutrition

The Medical Officer and Nursing Sister.—Generally speaking, at that time malnutrition was rarely considered as a cause of delayed convalescence or rehabilitation. The present emphasis in R.C.A.M.C. hospitals in paying particular attention to the food intakes and nutritional status of the individual patient was not widely recognized, and these and other points had to be stressed in educational programmes. For example, medical officers had to be told of the necessity for taking steps to see that patients were actually eating the food which had been ordered in the ward order books. This was essential, as we had observed in civilian hospitals²⁹ that, in general, a gross discrepancy existed between the surgeon's or physician's impression that an adequate diet was being ingested and the actual intake achieved by the patient. The following cases illustrate this point.

A patient in a surgical ward suffered from Pott's disease. Because of this and a prolonged attack of infective hepatitis he was placed on a high-protein diet. When his intake was measured it was found that he was getting only 86 g. of protein each day and 2,69 calories. Another patient was recovering from a compound fracture of the femur and developed jaundice. Orders were written for him to have a high-protein low-fat diet. When measurements were made he was found to be taking a relatively high-fat low-protein diet for his protein intake was only 67 g. a day. In neither instance had the discrepancies been noted by the attending medical officers.

The necessity for frequent consultations between the medical officer, the dietitian, and the nursing staff regarding special diets, special foods, and special feeding techniques for individual patients who required special nutritional care was also pointed out.

It was found, too, that, during their training, nursing sisters had not been taught the importance of ensuring adequate intakes of food in the average patient who was not subsisting on "special" diets. This was not surprising, since the medical profession has only recently recognized that ensuring adequate food intakes is a therapeutic measure which speeds recovery and rehabilitation. Consequently, nursing sisters, as in civilian life, looked upon feeding the patient as a routine measure and let the individual patient's appetite be the guide to intake. We therefore encouraged them to see that food was served hot and in an attractive manner, to offer second helpings, to persuade patients to eat, and generally to attend to the intake of protein foods by the individual patient.

The Patient.—The majority of patients correctly believed that the caloric requirements of a man in bed are much lower than those of a man doing work. But they made no distinction between the requirements for a healthy man lying in bed and those of a sick man in bed. The patient's appetite was poor immediately after trauma, operations, and burns, or during the acute phase of an illness. Poor appetites persisted, and patient got into the habit of not eating unless they were stimulated by attractive food, or through education, suggestion, or persuasion given by the attending medical officer. Patients often disturbed their appetite by eating chocolate, biscuits, and other confections just before or between meals. In summer, especially aerated soft drinks were consumed in large quantities and disturbed appetite considerably.

The Dietitian and Cooks.—Nearly all dietitians and cooks were anxious to prevent waste, and in some hospitals did not provide enough food. Consequently helpings served to the patients were often skimpy. There was also a tendency to serve too many stodgy and unappetizing dishes made from inexpensive types of food, such as bread and flour, in an effort to keep down costs. Such dishes contributed to much wastage on the plates.

The Hospital Administrative Staff.—The hospital administrative staff, quite rightly, attempted to keep costs down when purchasing food, but in a considerable number of hospitals the amount of money spent on raw foodstuffs was ludicrously small, and consequently food purchases did not cover nutritional requirements.

Spacing of Meals and Supplementary Feeding.—In many hospitals, although meals are supposed to be properly spaced,

found patients getting breakfast late in the morning and rich being served at noon or soon after. Since the midday meal was the main meal of the day, patients who had had a breakfast left food on their plates. The common practice of serving supper at 4.30 or 5 p.m. meant that many patients went without food, save for cocoa and biscuits, for 15 hours or longer. Supplementary feedings, such as egg-nogs, were used frequently. Water and sweetened orange juice were the main fluids provided at the bedside, and none of these drinks contributed much to either the caloric or the protein intake of the patient.

Equipment.—Special modern equipment, such as Hobart mixers, which help cooks and dietitians to prepare and serve attractive food, was often not in sufficient supply. Chipped white enamelware and cracked crockery, which was used occasionally in some hospitals, certainly did not stimulate the appetites of those who were ill.

Discussion

Peters⁶ points out that, despite the discovery of new agents and techniques which have reduced mortality, complications, and permanent disabilities, the overall duration of the period in hospital and of disability has not been reduced. He states that loss of strength and undernutrition were prominent among the factors which appeared to retard convalescence and rehabilitation.

In our experience many physicians and surgeons who regard loss of weight in hospital patients as inevitable explain wasting as "disease atrophy" or believe that most of the loss is due to harmless utilization of body stores of fat at a time when appetite is poor and the body requires some source of energy. The investigations of Shaffer and Coleman on typhoid fever⁷ in 1909 showed that the wasting which occurred in that disease was due to breakdown of protein tissue with excretion of large quantities of nitrogenous substances in the urine. Since then this phenomenon, which by long usage is still described as "toxic destruction of protein," has been shown to occur after burns,⁸ injury and elective operations,^{9,10} hemorrhage,¹¹ and other conditions.^{12,13}

In some patients the excretion of nitrogenous end-products is very large. Browne of McGill¹² reports excretions of between 25 and 35 g. of nitrogen in the urine each day in convalescent surgical patients. This is equivalent to the metabolic breakdown of $1\frac{1}{2}$ to $2\frac{1}{2}$ lb. (0.68–1.13 kg.) of muscle tissue. In one obese patient who suffered 20% burns marked weight-loss occurred. Investigation showed that he too was excreting nitrogenous waste products. This was the probable cause not only of the loss of weight but also of failure of skin grafts to take. Correction of his diet, which ensured large intakes of protein and cut down the overall nitrogenous loss from the body, resulted in a gain of $1\frac{1}{2}$ lb. (227 g.) a day in weight and considerable improvement in the appearance of the granulating areas. The next attempt at skin grafting was successful, and the grafts took excellently.

As yet there is no adequate explanation of the factors which produce the metabolic or "toxic" breakdown of protein that follows upon insult to the body. However, it is rational to associate it with the loss of strength, loss of weight, and atrophy which we have seen in patients in military hospitals. While no specific therapy is available to stop the body protein from breaking down, Taylor,¹⁴ Elman,¹⁵ Mulholland,¹⁶ Browne,² and others have all shown that the phenomenon can be controlled by adequate feeding, with larger quantities of protein and calories than has been the practice.

Taylor advocates¹⁴ a daily intake of about 2 to 3 g. of protein and between 50 and 60 calories per kilogramme of body weight (approximately 150 g. of protein and 3,500 calories for a 70-kg. man). In some individuals he has had to feed (by use of gavage or intravenous methods) up to 300 g. of protein a day to maintain body mass. Browne and his colleagues² suggest similar intakes of food to maintain adequate nutrition in the average hospital patient.

As the food intake of patients in R.C.A.M.C. hospitals in Canada fell short of the above-mentioned standards, and as so many of our soldiers were losing weight, a vigorous educational campaign was launched in the summer of 1944 to increase the intake of protein and calories. Studies¹⁷ made some eight

months later showed a satisfactory improvement (see Graph). These and other observations indicated that about 100 g. of protein and approximately 3,000 calories were probably as much as the average patient would consume at three meals by means of the ordinary diet, and that protein and calories above these amounts would have to be provided through supplementary feedings.

By the end of 1944 the Research and Development Branch of the Directorate General of Medical Services, in co-operation with the National Research Council of Canada, MacDonald College, and the Royal Victoria Hospital, McGill,^{18,19} had developed a satisfactory powdered high-protein milk-shake mix* with five assorted syrup flavourings which was easily reconstituted into a palatable and acceptable drink. The tinned powder stored well, could be made up in large quantities in the kitchen, and provided high food value in small bulk: this was also important, as the patient judged his food intake by volume rather than food value. By this means an extra 72 g. of protein and 1,100 calories could be given in the form of two small and one large milk shake taken during the day.

By clinical trial it was found that the most suitable routine was to serve the meals exactly at 7.30 a.m., 12 noon, and 5 p.m., and to give one 8-oz. (227-ml.) milk shake at 10 a.m. and another at 2.30 p.m. A 16-oz. (454-ml.) milk shake was taken at bedtime, usually 9 p.m. In some patients one or two of the supplementary feedings were omitted because it was considered that their requirements for protein and calories were at a lower level. It was found to be impracticable to give more than 8-oz. feedings at each of the two daytime supplementary feeds, as a larger quantity interfered with the appetite for the next meal. For the same reason it was imperative to ensure that the meals and supplementary feeds were served on time.

With increased food intakes, such as occur with the regime outlined above, clinical improvement in our military patients is noticeable. It is our belief that civilian patients would obtain similar benefits. Therefore we recommend adoption by civilian hospitals of the educational and catering programmes mentioned in this paper.

Summary

The cause for the loss of weight of patients in military hospitals in Canada has been investigated. Primarily this appears to depend on the "toxic" or metabolic destruction of body protein, but is aggravated by the inadequacy of the usual hospital diets. These diets were particularly inadequate in proteins and calories, having reference to the requirements of these patients.

The cause for the inadequate diets was found to lie in: (1) tendency of hospital staffs to economize; (2) lack of proper supervision of dietary intakes by the medical and nursing staffs; (3) improperly spaced meals and lack of appetizing dishes. Correction of these faults and the introduction of a high-protein milk shake raised the food consumption to satisfactory levels. The average maximum tolerable consumption has been defined.

The advisability of applying the lessons learned in military hospitals to civilian hospitals has been discussed.

THE ITCHY PATIENT

BY

HENRY MacCORMAC, C.B.E., M.D., F.R.C.P.

PAUL HARMER SANDIFER, M.R.C.P., D.P.M.

AND

ANTHONY MICHAEL JELLIFFE, M.B., B.S.

The skin has been picturesquely described as the mirror of the mind because it reflects the emotional state of the individual. This process is illustrated by such common phenomena as blushing with shame, blanching with fear, and sweating with anxiety. Other cutaneous responses may be peculiar to the individual—for example, in a subject who develops goose-flesh, accompanied by a feeling of "the teeth being set on edge," when an apple is peeled in her presence. A number of purely subjective cutaneous responses to emotion are also observed, including tingling and a sensation of warmth when the "start" reflex is excited, and "cold shivers" aroused by various emotions.

Itching may also be a manifestation of anxiety, as in one of our patients who would find himself scratching when under emotional stress; and in another, a worry-prone and eczematous individual, whose mental and physical disability disappeared after learning that his domestic and business problems had been solved.

Psychological Factors

The psychopathology of skin disease does not constitute a special problem; it is not fundamentally different from those disorders which it is now customary to call psychosomatic, and in this sense certain dermatoses are as much members of the group as asthma. Thus an attack of eczema may follow such diverse events as a near-miss by a bomb, worries over finance, besides contact with irritating solutions; for psychiatric investigation shows that in addition to a purely physical mechanism there are a great number of psychological factors which may operate in the production of those disorders of structure and function of body and mind which are covered by the term "psychosomatic."

Sir William Gowers's chapter on headache in his celebrated textbook may here be usefully recalled as illustrating psychological factors producing subjective sensations—e.g., itching. He calls attention to the effects of directing the thoughts to the vertex of the skull, pointing out the diverse unpleasant sensations which result from this exercise even after a short while. "It is easy," he adds, "to understand that such a sensation may be increased by constant attention, to an unpleasant and even distressing degree, especially if some real sensation originally 'drew' the attention to the part" (Gowers, 1888). This experiment can be applied to the skin: by focusing attention upon a selected area a sensation of itching may there be produced without any peripheral cause. With certain individuals obsessional preoccupation with some region of the skin, independent of or in association with minor skin disease, may be enough to evoke a sensory result at least similar to that produced by severe structural changes.

Physical Factors

Now itching, like pain, is a symptom which can be evoked at various levels of the nervous system; according to Walshe (1942) it is a variant of pain. Peripherally it may be excited by parasitic diseases such as scabies and pediculosis, or by systematized diseases such as psoriasis. At the cortical level it may be excited by such agents as cocaine. At the highest level, the level which it is convenient to regard as that of the mind, irritation may also originate. Even when moderate, itching can, if prolonged, occasion considerable distress; but when severe it becomes as tormenting as pain, and, like pain, may drive the unfortunate victim to almost any extremity. It compels the sufferer to inflict upon his skin secondary changes in the form of excoriations and a peculiar thickening, termed "lichenification." This latter symptom-complex, often referred to as neurodermatitis, might perhaps be better described as psychodermatitis. Patches of lichenification either may arise in an objectively normal skin as a result of itching and scratch-

ing or may appear as a complication of and an addition to an itching eruption. Lichenification is especially common atopic (allergic) eczema.

Treatment

It can therefore now be accepted that in the production of itching, as in the production of pain, both mental and physical factors are recognizable. When itching is physically determined, no more than local treatment, which removes the cause or restores the skin to its normal state, may be necessary. When psychological factors predominate, treatment of the individual as a whole calls for the co-operation of the psychiatrist. If, however, the urge to scratch can be, for a time at least, abolished by sedation or local therapy, "cure" may result because a vicious circle has been broken.

As a first trial in an endeavour to break a vicious circle sedation by intravenous medication was attempted. For this purpose one gramme of novocain in one litre of glucose-saline was delivered in a hundred-minute period into a vein daily for one week. This procedure was based upon the effect observed in the treatment of superficial burns—which, it was recorded, became insensitive for many hours—and upon effect noted in the control of the pruritus of jaundice (Gordon, 1944; Lundy, 1942; Tovell). Although itching could be allayed for 10 to 15 hours by this means the period was found to be too short to be effective, and as there was a risk of producing toxic effects larger doses were not favoured. Further, the procedure lacked any useful psychological effect.

For the second trial a form of chemical sedation was chosen which could be made to act longer with less risk of poisoning, having in addition a beneficial influence on the depression and anxiety so often present. There is nothing new in the principle Macbeth's desire for "sleep that knits up the ravel'd sleeve of care . . . balm of hurt minds" is probably as old as mankind. In the nineteenth century sedation by opium and inhaling ether and chloroform was employed in the treatment of mental illness. In the early twentieth century chloral and bromides were similarly used; and later barbiturates, which facilitated the development of continuous sleep, as a form of treatment. In applying a method of inducing continuous sleep for the relief of conditions characterized by itching it was hoped, in a series of cases, to achieve two ends: first, cessation of scratching, thereby permitting local healing; and, secondly, amelioration of the accompanying mental symptoms, thereby breaking the vicious circle of mental and physical distress, worry, depression, scratching, → increasing distress. When recognizing that this form of treatment has the disadvantage of being symptomatic, it has nevertheless been effective.

The technique of continuous narcosis followed that described by Sargent and Slater (1944), aiming at 20 hours' sleep out of the 24 over a period not longer than a fortnight. The main drug given, morning and evening, was "somniafina," and a supplementary drug paraldehyde. The results have seemed to us sufficiently instructive to warrant the description of a series of 17 cases. It should be clearly understood and emphasized that continuous narcosis is a dangerous form of treatment requiring experience and adequate nursing accommodation; first, to avoid mishaps which may even be lethal, and, second, to secure peaceful sleep of sufficient duration and depth to produce the desired object. It is undesirable to attempt continuous narcosis except under carefully selected conditions.

The series of cases treated and under review can be divided into four psychological groups, as follows:

1. Those who were psychologically normal and, if worried or depressed, were judged to show a normal reaction to the disability. This group numbered 5.
2. Those who showed mood disturbances which preceded exacerbations of the skin disorder, numbering 7.
3. Those in whom the relationship of the mood disturbance to the dermatosis was uncertain, numbering 3.
4. Those unclassified, because not examined psychiatrically, numbering 2.

Analysis of Cases

The accompanying table summarizes the clinical types, treatment, and the results of treatment. The association of mental and physical changes has long been recognized in what is called atopic eczema, "atopic" meaning strange or unusual, provided

Summary of Clinical Types, Treatment, and Results of Treatment

Case	Age (years)	Disease	Duration	Psychological Characters	Physical Characters	Narcosis	Mental Results	Physical Results
1 M	24	Atopic eczema	24 years	Cyclothymic type; depression precedes skin attack	Three weeks' severe exacerbation uninfluenced by rest and local applications	14 days; uneventful	Worry and depression relieved	Improved, and improvement maintained when reviewed after 6 months
2 M	25	"	25 "	Epileptic; cyclothymic type; mentally backward	Eruptions extensive and continuous	14 days	Less depressed	Improved, and improvement maintained
3 F	29	"	25 "	Worry-prone; anxiety exacerbates skin disease	Eruption almost constantly present over 25 years	10 days; uneventful	Improved	Improved, and improvement maintained when reviewed after 8 months
4 M	48	Eczema	5 "	Cyclothymic type; depression precedes skin aggravation	Eczema chiefly arms and face; recent intolerable itching	10 days; uneventful	"	Improved, and improvement maintained when reviewed after 4 months
5 M	39	"	15 "	No psychiatric examination	Chronic eczema hands and feet; recent exacerbation	6 days; patient uncooperative	—	Improved, and improvement maintained when reviewed after 3 months
6 F	41	"	6 mths.	"	Extensive eczema following scalded foot	11 days; uneventful	—	Improved, and relapsed. Systemic penicillin for sepsis of foot
7 M	43	Pruritus ani	2 years	Depression and anxiety secondary to disability	Pronounced objective condition	12 days; patient uncooperative	Improved	Unchanged
8 F	36	Pruritus ani et vulvae	8 "	Normal personality	Followed childbirth	10 days; patient uncooperative	—	Improved, and improvement maintained when reviewed after 2 months
9 F	41	"	7 "	Worry-prone; anxiety increases itching	Much aggravated after childbirth 2 years previously	11 days	Improved	Improved, and improvement partly maintained when reviewed after 5 months
10 M	34	Pruritus ani	7 "	Worry-prone; scratches under stress	Some perianal lichenization	14 days; patient uncooperative	"	Improved, and improvement maintained when reviewed after 2 months
11 F	42	Pruritus ani et vulvae	7 "	Cyclothymic type; depression and skin trouble not established	Infective eczema ano-genital region	8 days; stopped because of vomiting	Slight improvement	Slight improvement, not maintained
12 M	39	Generalized dermatitis	20 "	Normal personality	Better and worse over 20 years	10 days; uneventful	—	At first worse, then improvement, maintained when reviewed after 6 months
13 M	53	Exfoliative dermatitis	2 "	Depression secondary to disability	Intermittent attacks of dermatitis becoming exfoliative and generalized	10 days on 2 separate occasions	No change	After each narcosis improvement, then relapse
14 F	42	Psoriasis	38 "	Normal personality	Chronic psoriasis, becoming acute with violent itching	10 days	—	Itching relieved, psoriasis unchanged
15 F	53	"	13 "	Cyclothymic type; depression precedes exacerbations of psoriasis	Severe itching, 6 months, following gold injections for arthropathy	10 days	Less depressed	Slight decrease of itching
16 F	31	Atopic eczema	30 "	Cyclothymic type; relationship between skin disease and depression uncertain	Itching 1 year, began during pregnancy	5 days; patient uncooperative	Some improvement	Improved for 3 weeks only
17 F	40	General pruritus	1 year	Cyclothymic type; over-dependent	Itching with excoriations	5 days; patient uncooperative	Worse	No improvement

a convenient label for a group where eczematous reactions are found in association with the allergic disposition. Four of these cases are included in the series. Atopic eczema is a comparative rarity. As contrasted with common infantile eczema, which is without allergic affinities and almost always clears up by the second year, atopic eczema tends to settle early in the flexures of the elbows and knees and to continue to puberty or adolescence. In the severe forms the eruption becomes almost universal, with extensive secondary lichenization, persisting throughout life, with perhaps some degree of seasonal fluctuations—a variety often called Besnier's prurigo. No. 16 was an example of this severe type, and, apart from a temporary improvement, the record of failure is otherwise complete. In contrast, No. 2 improved both physically and mentally; this patient is now for the first time in his life in regular employment. An associated improvement in both the mental and the physical states was recorded in 7 cases (Nos. 1, 2, 3, 4, 7, 9, 10) and to a lesser degree in others (11, 15, and 16), which is evidence of the relationship between mental and physical states.

The cases under consideration include conditions with very different clinical characters; they have in common itching rising to such a degree as to require exceptional measures. Apart from this, their chronic and rebellious nature is revealed in the long duration—up to 38 years in one case. Taking into consideration these circumstances, improvement can only be relative, and in this sense most of the patients were relieved to a greater or lesser degree, and a crisis of almost insupportable itching, which was the motive for the continuous narcosis, was controlled.

Summary

Study of a group of itching dermatoses has shown that local treatment is adversely affected by scratching and by the psychological disturbances which commonly occur either as a prelude or as a sequel to the skin disease. These dermatoses are regarded as typical examples of psychosomatic disease.

A form of general treatment is described which has been found effective in controlling (1) the itching and scratching, and (2) the depression and anxiety, present in these cases.

In a series of 17 rebellious and chronic cases most of the patients were relieved after continuous narcosis.

No attempt was made to treat these patients by other than physical means. As they received no psychotherapy, treatment may be considered incomplete.

TROPICAL ULCERS AND PENICILLIN

BY

J. G. WEBB, M.B., B.Ch., D.T.M.&H.

Formerly S.M.O., Forward Area, British Military Mission to China

In South China tropical ulcers are a very common cause of suffering and disability, sometimes resulting in crippling and even death. The following notes, based on seven years' experience in that region, give some idea of the nature of these ulcers and of their remarkable response to treatment with penicillin.

Aetiology

The causative organisms are said to be Vincent's spirochaete and *B. fusiformis*. In smears of pus from the ulcers in the early stages I have constantly found *B. fusiformis*, but in only one case (not in the series here recorded) did I find spirochaetes as well. It is possible, then, either that the spirochaete is only occasionally present as an additional infection, or that it may occur only in the deeper tissues and not often appear in smears of the discharge. The finding of *B. fusiformis* in the smears has therefore been of diagnostic value, and indicates the response to treatment that may be expected.

The occurrence of the ulcers apparently depends on three factors:

1. *Portal of Entry for the Infection.*—This is usually the foot or lower leg, where any lesion, from an insect-bite to an extensive wound, may become infected. When ulcers occur on the hand the infection is usually secondary to scabies lesions between the fingers. Occasionally, in severely debilitated persons, they may occur on the outer side of the thigh, and these are the worst. Elsewhere on the body they are rare, as in the case of a man who had his scrotum pierced by a piece of sharp bamboo and developed an ulcer in the wound.

2. *Presence of the Infecting Organisms.*—The question arises whether these organisms live an active life outside the body and, if so, where their usual habitat is. Many of those with multiple ulcers on their legs are soldiers who are covered all over with scabies lesions and scratches, yet on the trunk these scratches do not develop into ulcers. Peasants and soldiers who constantly go through mud with bare feet most frequently develop tropical ulcers. It is very rare to find them in anyone who keeps his feet well washed.

3. *Poor Resistance to Infection.*—Tropical ulcers are rare in the robust. They occur usually in those who are undernourished and debilitated from disease; hence they sometimes appear almost like an epidemic among badly fed and disease-ridden Chinese troops.

large ulcer on the front of the leg, and, both during and after the healing stage, a recurrence of ulceration with fusiform bacillus infection is very probable.

The above description is of a severe ulcer, but many of them are comparatively benign. Some begin to heal when they are only half an inch (1.25 cm.) in diameter; in others the invasion progresses slowly over a period of weeks without surrounding inflammation or fever. However, there are three characteristics common to all these ulcers in the invasive stage: first, the progressive necrosis of skin and subcutaneous tissue; secondly, the blood-stained offensive discharge; thirdly, the presence in the pus smear of fusiform bacilli with or without a mixed infection of cocci.

Treatment

Until the arrival of penicillin the best treatment that I could find for the invasive stage was the application of magnesium sulphate paste to the cleaned ulcer twice a day. In the case of an acute ulcer this application is very painful for about half an hour, but the patient feels sufficient benefit to come back next day for treatment. After about four days the ulcer becomes clean, and in a week the healing stage may have begun.

Summary of Ten Cases of Tropical Ulcer

Case	Time from Onset to Start of Treatment	Site of Ulcers	Number of Ulcers	Size	Fever	Pus Smear	Treatment with Penicillin
A	One month	Scrotum	Single	1½ in. (3.8 cm.)	99° F. (37.2° C.)	Fusiform bac., few; mixed cocci +	Dressings; local injn., 10,000 units
B	3 days	Hands	Multiple	½ to 1 in. (1.27–2.54 cm.)	98.4° F. (36.9° C.)	Fusiform bac. +; mixed cocci, few	Dressings; I.M., 90,000 units
C	6 weeks	Legs	"	¾ to 1½ in. (1.9–3.8 cm.)	98.6° F. (37° C.)	Fusiform bac. ++; mixed cocci, few	Dressings only
D	4 days	"	"	¾ in. (1.9 cm.)	101.4° F. (38.5° C.)	Fusiform bac. only	Dressings; I.M., 90,000 units
E	Primary, 5 mths.; relapse, 7 days	Dorsum of foot	Single	2½ in. (6.3 cm.)	103° F. (39.4° C.)	Fusiform bac. ++; mixed cocci, few	" " "
F	2 weeks	Legs	Two	3 in. (7.6 cm.)	102° F. (38.9° C.)	Fusiform bac., few; mixed cocci +	Dressings; local injn., 10,000 units; I.M., 90,000 units
G	1 week	Legs and hands	Multiple	1 in. (2.54 cm.)	100.4° F. (38° C.)	Fusiform bac. +; mixed cocci +	Dressings; I.M., 60,000 units
H	6 weeks	Ankle	Single	1 in. (2.54 cm.)		Fusiform bac. only ++	Dressings; local injn., 10,000 units
I	Primary, 3 yrs.; relapse, 10 days	Leg	Two	2½ and 4 in. (6.3 and 10.3 cm.)	101° F. (38.3° C.)	Fusiform bac. only ++	Dressings; I.M., 75,000 units
J	3 days	Hands	Multiple	¾ to 1 in. (1.27–2.54 cm.)	99° F. (37.2° C.)	Fusiform bac. only	Dressings; I.M., 90,000 units

Yet I have not seen evidence of direct infection from one ulcer to another. Although ulcers may occur at any time in the year, there is a seasonal prevalence in August and September, when debility from malaria and dysentery is most widespread.

Clinical Manifestations

There are two definite stages in the progress of a tropical ulcer—that of invasion and that of healing. In the early stages of an acute ulcer there is a small black area of wet gangrene covered by cuticle only (the original wound, if small, has usually closed before the ulcer starts). This is surrounded by inflammation and oedema, which may extend over the whole foot or leg. The affected area is extremely painful and tender, and there is varying constitutional disturbance, which in severe cases amounts to a fever in the region of 103° F. (39.4° C.), and a muddy "toxic" complexion. In the course of a week or so the area of necrosis increases until it extends over perhaps one-third of the circumference of the limb or digit. The cuticle will have broken off in the early stages, and a copious blood-stained discharge of thick pus pours from the surface of the ulcer. It has a strong offensive odour which is characteristic and unforgettable. When the discharge is washed away the base of the lesion presents a ragged bleeding surface the colour of decomposing blood.

The edge of the ulcer is raised and indurated, except in very acute cases, when it is punched out. The necrosis is usually confined to the skin and subcutaneous tissues, but sometimes muscles, tendons, and even the bone may be invaded. Unless the tendons are involved there is seldom any tough adherent slough, and the invading organisms seem to have the power of complete cytolysis.

If the ulcer is untreated the length of the invasive stage and the extent of the damage are unpredictable. But the process will be arrested spontaneously, and the lesion then begins to heal—but slowly, owing to the induration of the underlying tissues. It may take years for skin to form completely over a

I have given 0.6 g. of intravenous neosarsphenamine in the early stage, and the invasion has progressed as if untreated. Sulphanilamide, whether administered internally or locally, has no beneficial effect that I have seen.

In May, 1945, a friend in the U.S.A.A.F. gave me a batch of penicillin to try out on special local diseases. I admitted 10 cases of tropical ulcer in the invasive stage and treated others as out-patients. Treatment with penicillin, even in the small doses to which we were restricted, had very good results. In one to three days, according to the severity of the case, the fever and the surrounding inflammation subsided, and the ulcer presented a smooth clean granulating surface. The inflammation disappeared so rapidly that the thick base of tough scar tissue which makes the healing of ulcers so slow did not form.

Penicillin was given locally and by injection. In every case a solution of 500 units per ml. in distilled water or saline (both were effective) was applied on gauze to the cleaned ulcer twice a day. In addition, all except the mild cases received intramuscular injections of 15,000 units three-hourly up to a maximum of 90,000 units. Two cases were given an injection of 10,000 units into the tissues beneath the base of the ulcer. The milder cases, which had only external applications, cleared up as quickly as those having injections.

Treatment in the healing stage is similar to that of varicose ulcers, in that rest in bed considerably hastens the healing, and, apart from skin grafting, the best local treatment is to bind the ulcer in elastoplast, which can be changed after seven to ten days.

Conclusion

The tropical ulcers of South China here described appear to be a pathological entity caused by infection with *B. fusiformis*. Penicillin has a powerful therapeutic action on them, and, when the drug becomes more widely available for their early treatment, an immeasurable amount of suffering and disability will no doubt be saved.

ANGIOBLASTOMA OF THE BREAST COMPLICATING PREGNANCY

BY

J. B. ENTICKNAP, M.B., B.S.

Late House-surgeon, Charing Cross Hospital

Since 1920 about one case of mammary haemangioma a year has been reported, in approximately equal numbers of cavernous and capillary types, and with evidence of malignancy in eight of these. Menville and Bloodgood (1933) describe eight examples, only one of which was malignant, in 3,000 consecutive breast biopsies examined histologically. As probably all angiomas, and not all carcinomas, would be examined, this may well be a high proportion. This is the only case treated at Charing Cross Hospital over a period in which about 1,000 breast tumours were seen. This suggests a general incidence of not more than 0.1% of all mammary neoplasms, while the incidence of malignant haemangioma may possibly be as low as 0.3%—truly a rare condition. No recorded case, however, appears to have been associated with pregnancy, nor has the tumour reached such an enormous size as this one; and the malignant cases were generally of much lower grade. These three factors may possibly be interrelated, and, I think, make this case worth recording. The high degree of clinical malignancy, shown by the rapid recurrence and fatal outcome within nine months, was not predictable on histological grounds. Microscopically there was actually very little tumour tissue to be seen, which explains the earlier biopsy being quite negative even after re-examination in the light of subsequent findings.

Menville and Bloodgood, in their review, point out that there is often enough clinical evidence for the diagnosis to be considered pre-operatively. Although this tumour was clinically atypical, the extremely rapid increase in size in April, due presumably to an interstitial haemorrhage, was suggestive.

It has long been recognized that pregnancy may be associated with a particularly virulent form of carcinoma of the breast, but here we have an example of the mesoblastic tissues undergoing a malignant change under the influence of pregnancy. There was probably a pre-existing simple angioma which was stimulated into activity by hormonal influences similar to those which possibly produce carcinomas. It seems less probable that the process is a two-step one, the epithelial tissues, themselves stimulated by circulating hormone, causing a local stimulation of the surrounding mesoblastic tissues; for then one would expect mammary angioma to be much commoner than the above figures suggest.

Report of Case

A primipara aged 20 was admitted on April 17, 1945, with an enormous tumour of the left breast. The patient became pregnant in October, 1944, and three months later first noticed that the breast was becoming hard. Ten days before admission, for a reason not then apparent, the breast rapidly swelled and became tense, painful, and discoloured. She had a swinging temperature up to 103°F. (39.4°C.), and her pulse rate was 120 a minute. A diagnosis of probable suppuration was made, but attempted aspiration yielded only blood, which on culture was sterile. It then seemed likely that the condition was a lactation carcinoma or a sarcoma, and the patient was transferred to Charing Cross Hospital for radiotherapy. She was immediately started, but the tumour continued to increase in size as judged by circumferential measurement. At this stage the appearance of the tumour was of a very large rounded mass, 72 cm. in circumference, in the position of the left breast. The thin overlying skin had ulcerated, the ulcers being produced by the coalescence of the original aspiration punctures, each of which had been stretched to form a circular hole by the rapid increase in size of the tumour. They were thus serpiginous in outline, the edges being free from the underlying tissue, which appeared to be organizing blood-clot.

The patient's general condition deteriorated steadily; her temperature remained high and her haemoglobin fell to only 4.8 g. % owing to several gross haemorrhages from and into the tumour. A biopsy was taken of the skin and underlying tissue and of material from the centre of the tumour, but no neoplastic cells were found, the sections showing suppurative reaction only. Local amputation after transfusion was decided upon, being performed on May 7 (by Mr. Norman C. Lake) under nitrous oxide anaesthesia with no ill effect

on the pregnancy. Her temperature immediately subsided, and her haemoglobin rose rapidly to 10.3 g. % on iron therapy.

Two weeks after operation a minute plum-coloured recurrence appeared in the scar. This resolved with radiotherapy, but recurred again, ulcerated, and bled. Subsequently a diffuse mass was felt in the right breast; this also disappeared on treatment. She had a forceps delivery of a healthy female child at full term—July 12—

Photomicrograph of the tumour

and was given testosterone to dry up the right breast. She was discharged to the out-patient department, but attended twice only. A follow-up showed that she went rapidly downhill and died on Sept. 13 from pneumonia consequent upon direct invasion of the lung, as shown by the fact that she suffered greatly from pleural pain. Necropsy was not performed.

At operation the tumour came away easily, but was found to infiltrate the pectoralis major over a small area. It was not possible to decide whether it originated in the muscle or infiltrated this from the breast. It weighed 2,400 g., had a maximum circumference of 75 cm., and on incision appeared macroscopically to consist entirely of semi-organized blood-clot.

The report on its morbid histology (Dr. H. W. C. Vines) was: "The growth is essentially haemangiomatous in type and has given rise to extensive haemorrhage. The appearances are fairly representative of a capillary angioma, but in some areas the cells are more anaplastic and a small number show mitoses. These are more suggestive of an angioblastoma, and it should be regarded as such."

I wish to thank Mr. Lake for his encouragement and permission to publish this case, and Dr. Vines for his pathological report and advice.

Medical Memoranda

A Case of Cerebral Malaria on Board a Troopship

The following case of cerebral malaria is thought worth recording because of the bizarre mode of onset. It should be explained that the ship left the United Kingdom with a large draft on board, and that on calling at a port in a highly malarious area a few personnel were embarked; these were berthed in scattered accommodation available through the ship.

CASE RECORD

When two days out from the malarious port a seaman aged 22 was brought into the troop hospital with the history that he had been found on the mess deck in a fit. The man was screaming and yelling, was throwing himself about, and had carpo-pedal spasms. He did not look ill; general physical examination was negative, his reflexes being normal but brisk. His pulse rate was 110; it was impossible to take his temperature. He appeared to be in a typical hysterical fit, and was treated as such, by slapping and cold water. He did not respond, and after about 20 minutes was given morphine 1/4 gr. (16 mg.) and scopolamine 1/150 gr. (0.43 mg.) and was restrained in a Neil-Robertson stretcher. In the meantime his messmates were again questioned, but nobody knew him. Eventually a man who had also embarked at this port stated that he thought the patient had been in hospital with malaria. Blood films were taken, and one of them showed a moderate number of M.T. rings.

The patient remained more or less in the same condition, though more quiet after the morphine. He was incontinent of urine and faeces. His temperature was now 101.6° F. (38.7° C.) and pulse 80. A rectal drip saline was started, and he was given quinine dihydrochloride 10 gr. (0.65 g.) intramuscularly. Under general anaesthesia (ether) a lumbar puncture was done; the fluid was not under pressure and was quite clear. Ten hours after the injection he had a convulsion. This consisted of the slow onset of tonic spasms of all his flexor and facial muscles; his jaw was firmly clenched, and he went black in the face. The spasms gradually relaxed, the whole convulsion lasting about 40-60 seconds. Two hours later he was given 8 gr. (0.55 g.) of quinine in 20 ml. of normal saline intravenously. Four hours and six hours after the intravenous quinine he had two more convulsions similar to the one described.

The next morning, 12 hours after the intravenous injection, he was given quinine 10 gr. (0.65 g.) intramuscularly, and this was repeated in 12 hours' time. He was now having very short periods when he was almost conscious, responding to external stimuli and talking disjointedly, but on each occasion he relapsed into coma. Altogether he was in a coma for approximately 50 hours. During all this time he was nursed in a Neil-Robertson stretcher, well padded. He retained his rectal salines reasonably well, and during any conscious periods fluids were given by mouth. His general condition was fairly good all through, though his pulse rate rose gradually and became very thready and rapid after convulsions. His temperature was irregularly remittant between 100 and 104° F. (37.8 and 40° C.). He was now conscious and was given quinine 10 gr. t.d.s. for the next four days, during which time his temperature settled, and he was put on to mepacrine. His condition gradually improved, and he was transferred to a shore hospital; on transfer he was still dazed and disorientated. He was seen five days later in hospital and had then fully recovered. His blood films were now all negative for malaria. On inquiry at the hospital six weeks later it was found that he had been discharged to sick leave fully recovered.

In all he had had three intramuscular injections of 10 gr. of quinine and one intravenous injection of 8 gr. at twelve-hourly intervals during his period of coma, followed by 10 gr. t.d.s. by mouth for four days.

G. D. S. BRIGGS, M.R.C.S.

Drug Eruption due to Sodium Pentothal

Pentothal anaesthesia is so safe and pleasant, from the viewpoint both of the patient and of the doctor, that it seems ungracious to draw attention to unpleasant side-effects associated with its use. These reactions appear to be decidedly rare when one considers the vast number of cases in which the drug is administered, and that harbiturates seem particularly liable to cause drug eruptions. Lundy (1942) stated that he had observed in some cases an urticarial reaction during anaesthesia with pentothal, while Hunter (1943) has seen urticaria and a rash resembling erythema multiforme after pentothal administration. Idiosyncrasy to the drug was seen in two cases by Davison (1943), a fine scarlatiniform rash with pyrexia appearing a few hours after the injection and disappearing in 48 hours.

In the case now reported the patient had developed on three occasions a punctate purpuric rash following the use of pentothal.

CASE REPORT

Capt. X., aged 24, though a fit and athletic young man, had been anaesthetized on many occasions. He had had chloroform once, ether-chloroform mixture twice, and nitrous oxide on several occasions with no ill effects. In December, 1943, he was given sodium pentothal before operation on a wound. Two days later a rash appeared on both flanks, the sides of the chest, and the lumbar region. There was no malaise, pruritus was not severe, and the rash faded within a week. In January, 1944, he was again wounded; pentothal was once more given, and an exactly similar rash appeared and faded within a week. In March, 1945, sodium pentothal was administered before tonsillectomy, and next evening a rash appeared over both inguinal regions and spread over the sides of the chest, affecting also the axillae and lumbar area. The eruption took the form of fine purpuric spots, and disappeared entirely within a week. The rash was not itchy, and apart from slight malaise there were no constitutional signs or symptoms.

As expected in this type of drug rash, patch, scratch, and intradermal skin tests, using 2.5% pentothal, were all negative.

Grateful acknowledgment for permission to publish this case is made to Col. W. J. F. Craig, O.B.E. (Officer Commanding a General Hospital at that time); Brig. G. Y. Fegetter (Consulting Surgeon, C.M.F., lately Officer i/c Surgical Division); and Dr. D. J. Collier (E.N.T. Specialist in charge of the patient).

Reviews

FRACTURES

A Complete Outline of Fractures. Including Fractures of the Skull. For Students and Practitioners. By J. Grant Bonnin, M.B., B.S., F.R.C.S. Second edition, revised and enlarged. (Pp. 658; illustrated. 30s.) London: William Heinemann. 1946.

The treatment of fractures has attracted a good deal of attention of late years and, despite its limited field, numerous monographs on the subject have appeared. The war has perhaps concentrated this interest and has certainly afforded an increase in experience of various methods.

The volume under review is a second edition of a work which first saw light in 1941. The book has been considerably enlarged in the process of revision and by the addition of chapters on open operations and war surgery. The section on fractures of the face and jaw has been rewritten by Mr. Barron. Injuries of the ankle are treated in greater detail, and this chapter contains observations on the mechanism of that joint which are of no little interest. The treatment of this important group of injuries is fully dealt with. The revision as a whole reflects, both in its convictions and in its precision of statement, the extended practical experience of the author. The use of local anaesthesia for the reduction of displacement is favoured in selected cases and under suitable conditions; an excellent outline is given of the methods advocated. The technical details of the use of plaster and other mechanical devices are clearly set out. The descriptive writing throughout is commendably clear and precise. Occasionally, as in the legend under Fig. 328, the author reverts to the old and confusing use of the term "extension" when traction is meant. The new chapter on open operations though short, contains a judicial and almost conservative survey of the subject. The author does not overlook the historic developments concerned, and in summing up the pro and cons of operative treatment he is well content to reproduce the conclusions of the B.M.A. Fracture Committee of 1910. The problem of fracture treatment in childhood is given due representation in the text as a whole. The process and results of osteogenesis in the growing bone present such differences from those in the adult that one may perhaps look for a special chapter on this subject in the next edition.

This volume is to be commended alike to student and to house officer: it will afford sound instruction for the first and reliable guidance for the second.

ENDOCRINOLOGY OF GESTATION

Endocrinologie de la Gestation. By Robert Courrier. (Pp. 396; illustrated. 465 francs.) Paris: Masson et Cie. 1945.

Prof. Courrier's name is well known for his work on sex endocrinology and his many writings on the subject in the years between the two wars. In this book—he brings together the results of his previous work and, fitting them into a review of the literature, presents a working picture of the hormone interplay which accompanies conception, pregnancy, and labour. The author points out that the writing of the book occupied several years, and during the later ones he was deprived of access to all except Continental literature. The book has not noticeably suffered on this account, and any omissions are to some extent compensated by the inclusion of some recent Continental references with which readers in this country may not be familiar. The subject-matter is concerned mainly with laboratory experiments, and, in applying them to the human being, due regard is paid to species differences. The book is arranged in five major sections, the first two being concerned with maturation and fertilization of the ovum, placenta formation, and the changes that occur in the various organs of the body during pregnancy. Then follows a brief account of the chemistry of the sex hormones and of their occurrence in body tissues and fluids during pregnancy. The author next deals with the factors concerned in the maintenance, prolongation, and termination of pregnancy. In the final section he sets out his concept of the hypophysial-corpora-luteum-placenta system and the part it plays in pregnancy, also mentioning the transmission of hormones through the placenta from mother to child and vice versa.

It seems fair to say that this book does not contain anything new, but it is a survey of present-day knowledge with an account of the main experimental findings on which that knowledge is based. None of the subjects is dealt with in any great detail and the bibliography has been kept within reasonable bounds. The illustrations are few and not of high quality, and the production is of utility grade. This, however, is not surprising when one thinks of the conditions under which it must have been prepared; indeed, the author is to be congratulated on having produced the book at all in what must have been difficult circumstances.

EVERYDAY PSYCHOLOGY

Abnormal Behaviour. By R. G. Gordon, M.D., D.Sc., F.R.C.P.Ed. (Pp. 75, 5s.) London: Medical Publications, Ltd. 1946.

It is still difficult to answer the question "Where can I find a sound commonsense book on practical psychology?" Dr. Gordon has already helped notably by his earlier book *The Neurotic Personality*. While on war service in West Africa, away from reference books and other psychiatrists, he wrote this little essay on commonplace abnormal behaviour from recollection of his long psychiatric experience. He is dealing here not with the criminal, the delinquent, or the nearly certifiable, but with the unhappy, aggressive, anxious or bag-ridden person whom we meet every day and whose tiresome peculiarities are mirrored faithfully, though perhaps not quite so intensely, in our own characters.

The first part of the book consists of 29 admirable pages on the normal, a subject to which psychiatrists have given practically no attention in the vast literature of their subject. In very small compass Dr. Gordon contrives to give the reader a clear inkling of what he means by behaviour, appetite, fear, conflict, responsibility, adjustment, and all the principal features of the normal psychological anatomy. Then he deals in the same commonsense language with the various types of abnormality—epileptic, cycloid, schizoid, and the rest—and sketches the common defence mechanisms of fantasy, depression, elation, suspicion, and so on with which we are wont to evade our problems. His chapter on bad habits is informed by a sane, positive humanity, and his account of mental deficiency reminds the layman of a factor which ought never to be, but which often is, forgotten in seeking for psychological causes. In dealing with lying, stealing, destructiveness, prostitution, and the other common forms of anti-social behaviour, Dr. Gordon shows his gift for putting a finger on the hub of a problem. In the final section on treatment, the department in which most writers on psychology betray their weakness, he contents himself with laying down general principles: positive, creative action rather than restriction and deterrence, and the need for knowledge, understanding, and love. It is hardly within his scope to indicate the manner in which these qualities can be profitably applied to particular types of abnormal behaviour. This application, the real difficulty, probably could not be taught by the longest book. In his opinion that no one in this country need feel out of reach of expert help he is perhaps optimistic, but it is typical of his practical mind that he gives the reader the address of the National Association of Mental Health as at any rate the first step.

V.D. IN GENERAL PRACTICE

Venereal Diseases in General Practice. By Svend Lomholt, M.D. With a Supplement on Penicillin, Mapharside, Sulphathiazole, etc. (Pp. 234; 39 illustrations in colour in 12 plates, 78 illustrations in black-and-white. 25s.) London: H. K. Lewis and Co. 1946.

Readers of this book by Svend Lomholt should note that it was completed before the war, which will explain why it does not appear to be up to date; this is compensated for by the inclusion of a supplement dealing with penicillin, intensive arsenotherapy, pyrethotherapy, the newer sulphonamides, and the culture of gonococci.

It is easy to see that Prof. Lomholt is primarily a dermatologist and syphilologist; the chapters on syphilis, particularly those on the various skin manifestations and their differential diagnosis, are quite outstanding, while the illustrations are first class; in fact, anything more nearly approaching the real thing than the coloured plates it would be hard to imagine. The three main venereal diseases—syphilis, gonorrhoea, and soft chancre—are dealt with on conventional lines, and the author's

views correspond very closely with those held and taught by most British venereologists; the concurrent-intermittent, and alternating-continuous methods of treating syphilis with arsenic and heavy metal are described and a preference is shown for the former. The value and importance of bismuth, a drug which has been rather underestimated in some countries, are very rightly stressed, while mercury is not considered so out-of-date as is sometimes suggested. With regard to gonorrhoea, the Neisser injection treatment is preferred to Janet irrigation as being more suitable for the patient to carry out himself. Other diseases which, though not necessarily venereal in origin, are commonly associated with V.D. include lymphogranuloma inguinale, granuloma venereum inguinale, balanoposthitis, herpes genitalis, condylomata acuminata, and simple (non-gonococcal) urethritis; these are dealt with very briefly. *Trichomonas vaginitis* is not mentioned.

It can be said without hesitation that the teaching of this book is eminently sound and many pearls of wisdom are included; nevertheless, there are many points which call for criticism. The author has an excellent knowledge of English but is not completely master of it, with the result that curious words, such as "clinician," are included and others—e.g., phenomena—are repeated *ad nauseam*. It might have been better if the original had been translated into English by an Englishman. The description of the Wassermann test is far from good, and much more might have been said about the incidence of false positive reactions; the Lange reaction is not considered worth while, and only tertian (presumably benign) malaria is mentioned in the treatment of G.P.I., nor is trypanamide advocated in addition. There are several serious errors. The amboceptor used in the complement-fixation test for gonorrhoea is not "the inactivated serum of rabbits treated with injections of an extract of guinea-pig kidney" (p. 175), at least not in Great Britain; and to give a dose of 0.15 g. of neoarsphenamine (p. 124) to a patient who had suffered from a severe arsenical dermatitis seems like asking for trouble. There are between twenty and thirty typographical errors which suggest that the proof reader or the printer is more blameworthy than the author. The general format of this book, the paper, and the clarity of the print are excellent, but the cover suggests continuous forked lightning or an attempt to present jazz music in a visible form and is bizarre.

Notes on Books

A B C of Medical Treatment, by Dr. E. NOBLE CHAMBERLAIN, is published in London by Oxford Medical Publications at 10s. 6d. The first impression left by this concise and excellently arranged little book might be that no qualified medical man should need it—an impression from which one cannot wholly escape while at the same time paying tribute to the care and skill with which it has been compiled. As will be seen, our criticism is directed against practitioners as the author appears to know them, rather than against the author.

Mr. H. W. L. MOLESWORTH has prepared a second edition of his small book *Regional Anaesthesia* to replace copies destroyed by enemy action. In revising it he has stuck to his original plan of relying on his personal experiences in the practice of a general surgeon. The publishers are H. K. Lewis and Co., and the price is 8s. 6d.

The proceedings of a conference on science and human welfare held last February in London have been published by the Temple Fortune Press (Mildner Works, Herbal Hill, London, E.C.1) at 2s. 6d. The conference was sponsored by the Association of Scientific Workers, supported by a number of other bodies, including the Physical Society and the Nutrition Society. Among the contributors are Sir Robert Robinson, Sir Robert Watson-Watt, Prof. A. V. Hill, Dr. Julian Huxley, and Mr. F. Le Gros Clark.

The February and April numbers of the *Surgical Clinics of North America* are now available in book form from W. B. Saunders Company, London and Philadelphia. The first is a Chicago number comprising a symposium on surgical technique, in which a group of surgeons, active in several fields, discuss their methods in a variety of operations. The second volume, a New York number, presents a symposium on surgical diagnosis, with six additional papers on other subjects. The main symposium, discussing some of the commoner problems of diagnosis, is chiefly by surgeons in the New York area, but there are also papers from the Montreal General Hospital and McGill group and from surgeons in the Services. Six numbers of the *Surgical Clinics* are published each year; the annual subscription is 55s. (paper covers), and 75s. (cloth covers).

Nova et Vetera

PHYSIOLOGY OLD AND NEW

Celsus said that Hippocrates' confession of a mistake in diagnosis was "more scilicet magnorum virorum et fiduciam magnarum rerum habentium." An associated trait of moral and intellectual greatness is shown by how a man whose scientific researches are epoch-making speaks of long-dead and largely forgotten predecessors who failed where he has succeeded. Small men speak with contemptuous pity of remote predecessors, great men respect them; Harvey and Newton deeply respected men whose conclusions they disproved; they recognized their peers.

These reflections are suggested by a perusal of Sir Charles Sherrington's monograph on Jean Fernel,¹ the shadow of a name to most physicians and physiologists of our time. It is a model of how one great man appraises another. Fernel was the first writer to entitle a treatise *Physiology*; we may call him a physiologist, although to his contemporaries he was primarily known as a wise physician. Between a Fernel and a Sherrington there is a great gulf set; it is not only that a physiologist of the 20th century knows much that was unknown and unknowable in the 16th century; there is a spiritual difference. As an individual human being Fernel was, if possible, as modest as Sherrington (who, in his exposition of what all the world now believes about the central nervous system, never even hints how much of this knowledge the world owes to him). Though his undergraduate career was successful, Fernel was dissatisfied with himself and determined to become better acquainted with the old masters of philosophy and science; geometry attracted him—as it had attracted Galen 1,300 years before—and his first book, published when he was 30, was mathematical. Three years later he graduated in medicine, in 1530. At first Fernel may have thought that in astrology—which made a subtle appeal to both the logical and emotional sides of the human soul—he had the key of medicine. But, just as his intellectual honesty had earlier led to doubt of the sufficiency of what we perhaps should call pre-clinical medical training, so increasing experience of clinical medicine made him doubt the value of judicial astrology, and his *Physiology*, published in 1542, is "altogether restrained as to astrology." The time was to come when he "condemned astrology utterly, with its genitures and divinings invented from the stars by the superstitious, and giving predictions of I-know-not-what portents and falsehoods."

But though Fernel was, as an individual human being, humble, he did share the intellectual arrogance or, perhaps it would be better to say, confidence of the Greeks that thinking could solve all the problems of Nature.

"Physiology in the treatise of Fernel is an orderly, logically constructed subject, so rounded-off that few loose ends remain to it, and hardly a growing-point. It is suspiciously complete. The four elements by their four qualities introduce the temperaments, the temperaments invite the humours, the coctions presuppose the organs, the organs require the spiritus, the innate heat demands the heart, the faculties consummate the occult, and are themselves consummated by—crowning concept—the 'life-soul,' the *anima*. In result, that which was to be demonstrated is demonstrated, Q.E.D. Contrasted with this self-contained theorem, the physiology of to-day appears a thing of patches, ragged, untidy, fringed with loose ends, amorphous, confessing uncertainties, but, on the other hand, bristling with facts and growing-points. And, by comparison with Fernel's, how versed in Nature, how capable in daily life, how relatively effective in the sick room!" In fact, "The system which Fernel unfolded was logical but artificial, too humanly logical to resemble Nature."

Fernel, though a humbler individual than Galen, did have Galen's pride in the intellect of man. To Galen, the apostle's dictum that "the foolishness of God is wiser than men: and the weakness of God is stronger than men" would not have appealed even if for "God" one read "Nature." Yet Galen did write of the creative power of Nature:

"Aristotle dealing with this very subject, wondered whether there was not a beginning more divine, something greater than just heat

and cold and moist and dry. Wherefore I think it wrong of men to draw such rash conclusions in matters so great and assign to the qualities alone the power of shaping the parts. It is possible that these are nothing more than the instruments and something else the master-hand."

There is no doubt that, in his practice, Fernel gave more weight to practical experience than theory. This, according to his pupil and house-mate Plancy, was his view of how one should become a physician:

"After a thorough grounding in the principles and elements of philosophy, to learn straightway from some terse and well-written medical précis such details as have to be known of the nature of the human body; then to master the flavours, powers, and virtue of medicaments simple and compound; and then to learn to distinguish the signs and symptoms of the several diseases and their causes, and to gather these together, as a store within the memory then, finally, to follow, long and attentively, the art of practice of some elderly practitioner, capable and experienced in treatment, and to observe in the sick patients themselves what you have read in the books and heard in the lecture-room. He held that there was much in the theoretical part of medicine which could not be explained truly, nor understood, except by way of long practice and experience. He judged that no one can get through on books alone; numerous although books are. The best instructors in medicine were, in his view, practice and experience; they clear up the obscure and equivocal which so embarrass and obstruct the beginner, and they fortify him."

Fernel, who had for years eluded his king's desire to have him physician-in-chief, had yielded in 1556 and was in attendance on Henry in the campaign against the English; he returned to Fontainebleau after the fall of Calais on Jan. 1, 1558; in the early spring his wife fell sick of fever and died; he soon fell sick, and died on April 23. He was probably 61. Perhaps enough has been said to encourage a reader to obtain Sir Charles Sherrington's monograph, although nothing has been said of the scholarly care with which the author has verified every detail, in a way which would have been creditable to a young historian at work in peacetime.

M. G.

EARLY MEDICINE IN ASSYRIA AND BABYLON

La Médecine en Assyrie et en Babylonie, by Georges Contenau (Paris: Librairie Maloine). This book deals with the dawn of medical civilization. Little is known of this period (4,000 B.C. of the Assyrian and Babylonian regions, for up till then writing had not been invented. By the third millennium history marks its records of the political struggles between Sumerians and Semites on cuneiform clay tablets. The second and first thousand years B.C. saw much rivalry between these two kingdoms, and it is chiefly this period which Dr. Contenau describes in all its aspects, including the famous Hammurabi code of Babylonian law. It is interesting to note, even then, the distinction made between medicine and surgery. State medicine under this code flourished throughout the land, though, under the system of theocracy, medical men were sacred until they began to practise surgery, which then brought them into the code. Medical secrecy was insisted on: "to repeat to the King what a doctor has been told, even under oath, is punishable by death."

Minor surgery was practised by barbers. Much palaeo-ethnological work done by Keith, Buxton, and other British scientists has proved, by craniology, the racial differences between Occidental and Asiatic peoples. The two leading types were dolicocephalic and brachycephalic, but transitions between them have also been found in mummies and other remains. Physiology was non-existent; the heart was believed to be the seat of the soul, and the kidneys of bodily vigour; the liver was concerned with the emotions and was also the seat of life. In the list of foods used by these early races (3,000 B.C.) we see that they are similar to those eaten by the fellaheen of to-day.

Dr. Contenau, who has already written thirteen books on Oriental antiquities, has brought his wide experience and powers of clear exposition to make this a useful and readable volume on this particular subject.

SAMPLE SURVEYS

The growth of the modern State since the development of the industrial revolution, to go no further back in time, has led, and now almost daily leads, to a further and further extension of State control over our habits and actions. The political hue of the Government in power may dictate the degree of control which is regarded as desirable at a particular point of time, but, whatever the hue, it seems inevitable that authority, both central and local, will legislate increasingly on a wide range of subjects which affect all citizens, or sometimes a particular class of citizens, throughout their daily lives. That being the situation, whether we like it or not, it is certain that the better informed these authorities are the more appropriately will they frame their laws and regulations. It will be of benefit to them to know what the man-in-the-street and the housewife in the home think of their plans, though good government must often guide and lead rather than follow public opinion. Of still greater benefit will be factual information bearing on the proposed line of action; without such knowledge State direction will not only frequently fail but will damage rather than assist the society it governs. One of the difficulties in the modern State is to secure this information over the vast range of subjects involved. There is a limit to the census technique, whether it be a census of population, production, or distribution. Such methods to cover the whole population can be employed only at relatively wide intervals of time, some 5 or 10 years, and the amount of information that can be demanded of the form-filler must not go too far. A still stricter limit should be laid upon the present popular habit of distributing questionnaires from the hundred and one interested parties to the ten thousand and one uninterested.

The modern development is, therefore, turning more and more towards the sample survey in which a trained interviewer, emulating the Ancient Mariner who "stoppeth one of three," approaches a randomly selected sample of the population and extracts the required information by a series of ingenious, and sometimes ingenuous, questions. Experience shows that up till now this method is successful in so far as refusal to take part in an inquiry is limited to some half per cent. of those approached, whereas up to 50% may consign a questionnaire to the waste-paper basket and thus vitiate the returns. But, clearly, too wide a development of this relatively new technique may lead to an increasing revolt on the part of Mr. John Doe and Mrs. Richard Roe, and the third or fourth earnest seeker after truth will be told what to do with his or her form

and not always politely. There is need, as PEP stresses in a recently issued broadsheet,¹ for co-ordination in this field, co-ordination between Government Departments, between the central and local authorities, and between these and scientific and social institutions, university departments, and commercial organizations. Without such co-ordination there is bound to be not only an overlapping of inquiries and much wasted effort, but a cluttering up of the field with technically inefficient investigations and with conflicting results due to a lack of agreed definitions and methodology. There is, however, no doubt that in this sampling of human populations for the purpose of obtaining factual data and, rather more doubtfully, opinions lies an important development of social and statistical work in the next few years. PEP's broadsheet is, therefore, a timely and valuable discussion of its problems.

Initially, it defines the Social Survey as an objective and unbiased investigation of habits, environment, or views of a group of people (in total or a sample) through investigators going to the people themselves, in their homes, workplaces, or elsewhere. Two fundamental points are rightly stressed: the selection of a sample that is representative—not at all an easy task in practice; and the framing of questions to which the answers will in the main be trustworthy—an even more difficult job. In both these aspects fundamental research is urgently required: for example, how far the opinions of the interviewed, or even their apparently factual data, may be distorted by the technique of the interviewer or emotionally coloured through his, or her, own opinions on the subject. There is, indeed, already some evidence that this is a factor to be watched and guarded against if true objectivity is to be attained. Obtaining an originally unbiased sample may sometimes be relatively easy, sometimes very difficult, sometimes quite impossible. For instance, a good sample of men serving in an R.A.F. command might well be based upon the fact that each man has an individual number. A sample of 1 in 10 might, therefore, be extracted by merely taking those whose numbers end in the digit 6, or 1 in 100 by taking those whose numbers end in 66. To secure a sample of 3,000 from a population of 45 millions is not nearly so simple. It is usually based upon a choice of "representative" areas of the country in their correct proportion and then a random selection of persons within each. Research into this methodology is needed. Practical difficulties continually arise in samplings of human populations.

Another factor to which PEP draws attention is memory. To what extent will the interviewed accurately recall the event to which their cross-examination is being directed—for instance, their sickness experience in the past months, the age at which their children were immunized, their breakages of domestic crockery over some interval of time? All this needs much thought and the introduction of checks for the consistency and "reasonability" of the data. PEP is, perhaps, a little optimistic in affirming that most people can describe correctly what they have eaten in the previous 24 hours, and that the housewife can remember to a few days when the supply of milk was

¹ *The Social Use of Sample Surveys*. Broadsheet No. 250; 1s. 10d. including postage, from PEP, 16, Queen Anne's Gate, S.W.1.

cut, although it happened three months previously. Again, there is scope for research and the accumulation of accurate evidence to justify such assertions.

Much of the broadsheet is given to a useful account of the Government's wartime developments in this field through its Wartime Social Survey. With a large field staff and relatively small headquarters staff for the analysis and reporting of the results, it has been continually, and to a large extent successfully, active on behalf of Government Departments. To take a few examples: it has studied the impact of propaganda upon the population—e.g., the kitchen front, diphtheria immunization, venereal diseases, and "coughs and sneezes spread diseases." For the Board of Trade it has kept a continual eye upon clothing needs and shortages, and the supply of various household goods and demand for them. On behalf of central and local authorities it has made surveys of housing problems, lighting and heating, and the planning of estates. Other important subject-matters include an inquiry into the occupations of old people, journeys to and from work, the social dislocation due to aerial attack, road accidents, and a monthly index of national morbidity to supplement the mortality data upon which our evidence of the health of the nation is to-day principally based. All such work has been based upon samples of the whole population. Much of it is clearly devoted to *ad hoc* inquiries, some limited to the war conditions; but with increasing Government intervention there is likely to be more rather than less of them needed in future, and, as already said, an urgent need for deeper research into the foundations of the method and its various characteristics. Given more freedom to carry out this research, there is a strong case, as PEP urges, for the permanent retention of this Governmental Survey Unit, not necessarily with a monopoly of Government work, and to a large extent carrying out its tasks in close collaboration with other organizations—learned societies, universities, and other institutions. By the publication and open discussion of its results (so far hardly attempted) a higher standard of work will be achieved and the use of more efficient techniques be introduced. Government assistance is essential because wide-scale inquiries, necessary to ensure satisfactory sampling, are expensive and time-consuming.

To those who object to samples it should suffice to point out that many of our beliefs and conclusions must be necessarily based upon them. The cost-of-living index is derived from a sample of working-class budgets; dietary studies are made on a sample of families (and not at all likely to be representative); the efficiency of a method of treatment is judged upon a sample of patients, and so on. The problem is to get the right sample. Even at its lowest the Social Survey may achieve the success of the U.S.A. Office of War Information, which, PEP reports, numbered among its noblest ventures the demonstration that a new income-tax form was incomprehensible to a substantial part of the public. "As a result of this survey a new form was devised which everyone could understand"—certainly no mean achievement—"and the Treasury gained millions of dollars from the increased revenue." This at least should touch the heart, and pocket, of the Chancellor of the Exchequer, and ensure the future of the Social Survey and the right development of its techniques and uses.

PENICILLIN: D-DAY TO VE-DAY

Under the title *Penicillin Therapy and Control in 21 Arm Group* there has been published in book form¹ a series of 60 individual reports on the use of penicillin for treating wounds or disease, all based on experience on the Continent between the landing in Normandy and the end of the war with Germany. Those dealing with wounds are the product of a planned investigation organized by the consulting surgeon, Brig. A. E. Porritt, and the adviser in penicillin and chemotherapy, Lieut.-Col. G. A. G. Mitchell, which sought answers to 17 specific questions. Readers interested in the surgery of trauma will find a wealth of material here, including masses of statistics, from which to draw their own conclusions about how to combat sepsis. There is general agreement that penicillin was more effective than any of the "contrast agents" (chiefly sulphoamides and acridines) in preventing wound infection, and most surgeons credit it with an important share in the vast improved results obtained in this campaign, though rapid evacuation, resuscitation measures, and first-class surgery are also largely accountable for them. How good the results were may be gathered from a table in an appendix giving the mortality of different types of wound, based on almost complete returns for the whole campaign. Among 50,201 casualties the deaths totalled only 2,564, and in many categories, including most open fractures and joint injuries, the recoveries were over 99%. It seems also to have been fairly generally agreed that combined sulphonamide treatment added little if anything to the protection obtainable with penicillin. Most surgeons found the clinical condition of the wound a better guide to treatment than a bacteriological report, and were willing to do without the latter. An interesting feature is the improved results obtained in abdominal wounds: it was doubtless a mistake to regard penicillin as inapplicable to wounds involving the bowel because some of the bacteria more easily cultivated from faeces are insensitive to or destroy it. If *B. coli* was in fact the chief cause of peritonitis after a perforated bowel, penicillin would be of little use in preventing or treating it, but anyone who has examined the exudate in such cases by rather more thorough methods than usually known that many other bacteria are often concerned, some of which belong to generally penicillin-sensitive genera. There is much else to be learned from this section of the book about the technique for treating wounds involving different structures. The reader has to delve for it: there is no summary of the whole of this material, with the result that it is somewhat fragmentary and repetitive.

The medical and laboratory section contains reports on an almost bewildering variety of subjects: some of these are the treatment of venereal disease, Vincent's gingivitis, skin diseases, staphylococcal septicaemia, and Weil's disease, the distribution of penicillin in the body, its stability in various preparations, and matters of technique in administration. This is by far the most important publication on penicillin since the special number of the *British Journal of Surgery* devoted to it in 1944, and makes public for the first time a mass of Army experience previously available only to those with access to confidential reports. Its interest

¹ Published under the direction of the Director of Medical Services, 21 Arm Group, 1945.

ot ceased with the end of the war, for surely there are lessons here which should be applied in civilian practice? Penicillin will now be used with increasing freedom for preventing sepsis after injuries of all kinds. Perhaps the most important question in this connexion is one which his book does not answer: is it possible to achieve good results by the simple and economical method of local application? There were indications in much earlier Army observations, including those made in 1943 by Cairns and Florey, that early penicillin powder treatment reduced the frequency of sepsis. The applicability of this method to civilian casualty work seems a subject worthy of study.

HEREDITY IN EXOPHTHALMIC AND NODULAR GOITRE

It has from time to time been pointed out that heredity may be a factor in the causation of goitre, though little seems to have been done in the way of large-scale or systematic studies. A recent paper by Martin¹ is therefore particularly welcome. His series is relatively large and he is able to put forward a plausible genetic hypothesis which can be readily tested in future investigations. He classifies his cases into two groups: (1) primary exophthalmic goitre; (2) nodular goitre, whether toxic or non-toxic. He argues that toxic and non-toxic nodular goitres alike arise from simple colloid goitres, that it is sometimes difficult to separate toxic from non-toxic cases, and that thyrotoxicosis may supervene at any time in the possessor of a nodular goitre. This broad distinction certainly appears to fit the genetics of these conditions and is largely responsible for the relatively clear-cut results.

The sample included 90 cases of primary thyrotoxicosis and 111 cases of nodular goitre. The striking finding in the former category is that there is a definite familial incidence—i.e., affected sibs occur much more often than affected parents or children. This points to the action of a recessive gene. Inquiries were not made as to consanguineous union among the parents. It is unlikely, however, that much would have been revealed; in so common a disease the excess of cousin marriages would be small and very large numbers would be required in order to demonstrate it. It is suggested in a genetical note by R. A. Fisher that there is strong evidence for a single recessive gene favourable to the disease, and perhaps necessary for its occurrence, and that, if this is the case, of those potentially abnormal about half the females and a quarter of the males actually develop the disease. Primary exophthalmic goitre is now widely considered to be a psychosomatic condition and not primarily a disease of the thyroid gland. The well-known role of mental shock, infection, and so forth in precipitating the disease could be fitted into this genetic scheme, for something is needed in addition to the genetic factor before the disease can become manifest. A recessive factor with a frequency of manifestation in women of 70% to 80% is also the hypothesis of Bartels, whose work is quoted by Martin in an appendix. Bartels' survey was made in Copenhagen, and is, in Martin's opinion, somewhat complicated in interpretation by the grouping together of primary and secondary toxic cases.

It is possible that the hypothesis may turn out to be too simple. One difficulty in Martin's figures is the peculiar sex-ratio of affected persons among the sibs of the original cases. The sex incidence of toxic goitre is well known. The Registrar-General's figures for deaths show a constant ratio of 7 or 8 women for every man. This is also true of

morbidity. Julia Bell² found almost exactly seven to one in a sample of some 1,200 hospital in-patients. Martin's original index cases show just the same sex-ratio, yet among the sibs affected men are nearly as common as affected women. The discrepancy is highly significant and raises the doubt that there may be something peculiar about his sample.

The incidence of thyrotoxicosis is affected by race. An admirable and detailed study by McEwan³ gives the distribution of deaths in 1936 for England and Wales. It was pointed out by Fraser Roberts⁴ that McEwan's maps bore a startling resemblance to ethnographical maps showing stature, brunetteness, and the like. He showed that the correlation between McEwan's figures for counties in 1936 and the "index of nigrescence" in Beddoes' *Races of Britain* of 1885 was no less than 0.42. It may be that the recessive gene is commoner among the Celtic peoples of these islands, or perhaps it is the frequency of manifestation which is different. Either result would appear somewhat unusual, though by no means impossible.

The distinction between primary thyrotoxicosis and nodular goitre seems largely justified, though on the figures presented it is not perfectly clear-cut; moreover, the sex-ratio is just the same as in toxic cases. In nodular goitre there is no suggestion of a familial incidence. Affected relatives of all kinds are commoner than in the general population, but in view of the complexities due to such factors as iodine deficiency, Martin hesitates to conclude that his results provide any evidence in favour of a genetic basis for this variety of goitre.

The results of this study are suggestive rather than conclusive. They have the great merit of pointing the way to future studies on a larger scale.

OESTROGENS FOR PROSTATIC CANCER

That oestrogens improve the lot of certain patients with carcinoma of the prostate is now well established, but little is known of the manner in which the hormones influence the neoplastic tissue, or of the process of retrogression which the tumour undergoes, and no exact measure is available for assessing the effect of therapy. Schenken, Burns, and Kahle⁵ recorded histological comparisons of material removed from malignant prostates by repeated transurethral resection during the first two months of treatment. Fergusson and Pagel⁶ have correlated the clinical and biological findings with the histological progress of the disease as illustrated by serial biopsy over periods of six months to two years.

Not all cases of prostatic cancer are suitable for an investigation of this character. Some patients are too ill to permit serial biopsy and others are too well to require it. Fergusson and Pagel's necessarily small series is thus not free from the defect of selection. They studied five patients; four were treated with stilboestrol and one with dienoestrol, and all were subjected to repeated transurethral resection by the Gershom-Thompson cold punch. On each occasion the material resected was studied histologically. Progressive alterations in the architecture of the tumour are shown by tables, graphs, and photomicrographs. The cytological changes included (1) a progressive reduction in the number—and usually also in the size—of tumour units per square millimetre, (2) pyknosis, (3) concentration of nuclear chromatin, and (4) a reduction in nuclear diameter. The first and last of these effects can be mathematically expressed and may be used to measure the effect

of oestrogen therapy, provided the sections are removed always from the same locality and provided the effects of repeated trauma can be neglected. Fergusson and Pagel claim to show only that regressive histological changes are a fairly constant accompaniment of oestrogen therapy—in none of their five cases did carcinoma disappear from the samples of tissue removed. They concede that in other patients, whose favourable progress excluded them from the series investigated, a complete resolution of symptoms may have been the expression of "cure," but they demand more direct evidence of this favourable result than is at present available.

The same authors regard the level of the serum acid phosphatase as the most valuable measure of the efficacy of the oestrogens in any individual case of prostatic cancer. The persistence of an elevated serum acid phosphatase, despite massive doses of oestrogens, suggests that prostatic epithelial activity remains unchecked and the histological picture correspondingly unaltered. The degree of elevation of the serum acid phosphatase represents the general activity of all deposits of tumour, both primary and secondary, for the phosphatase content of resected fragments of prostate bore no constant relation to the serum value. Fergusson and Pagel have shown that the response of prostatic cancer to oestrogen treatment offers a broad opportunity to the pathologist no less than to the surgeon and the chemist. The next phase in our growing knowledge of cancer may well centre in the prostate. The histological nature of tumour regression, until recently one of the rarest of pathological phenomena, is transcended in interest only by the chemical process which brings about regression. It is fortunate that a disease which so invites repeated histological study should, almost alone among tumours, sometimes require repeated biopsy as a standard method of treatment.

DECORTICATION IN ACUTE EMPYEMA

An advance in surgical treatment that has emerged from the war is the use of decortication in the management of clotted haemothorax and of infected haemothorax. If ineffective conservative treatment is continued in these cases the time spent in hospital may be long, and permanent disability may ensue. A covering of organized exudate prevents the lung from expanding, and a fixed contracted chest with crowded ribs and severe scoliosis result. By decortication the lung is freed and can be made to fill the chest completely, or only a small residual space is left which can be obliterated by a few days of post-operative suction. Healing is achieved in most cases in a short time, and a virtually normal chest results, the severe crippling of a "frozen" chest, or of total thoracoplasty, being avoided. The importance of decortication in haemothorax has been stressed by Lush, Nicholson, and Stevenson,¹ by d'Abreu, Litchfield, and Hodson,² and by Barrett.³

Price Thomas and Cleland⁴ have given a detailed account of the management of these cases, and have applied the same principles to the treatment of other forms of acute empyema. For most cases orthodox methods of drainage suffice—namely, drainage by rib resection, removal of all fibrin clots, and encouragement of lung expansion by proper breathing exercises and early mobilization of the patient. There are two conditions, however, in which chronicity threatens: total empyema in which the upper lobe is often not only unexpanded but has fallen down over the lower lobe; and multilocular empyema. Decortication

can prevent this and lead to healing in a very short time. Open thoracotomy is essential, either by resection of a long segment of a rib or by a long incision in the sixth inter-space. Intratracheal anaesthesia is needed, and a blood transfusion must be given during the operation. Decortication in acute empyema may be more difficult than in clotted haemothorax, and may be accompanied by much oozing. The whole lung, including the interlobar fissures, must be freed and by positive pressure must be made to fill the chest, which is then closed with a basal and an apical suction catheter. Sanger⁵ prefers to use two anterior and two posterior suction catheters, which can be removed in two to four days.

Penicillin has made this procedure possible in severely infected cases. Even so, as the operation is a severe one it is unsuitable for many patients with acute empyema who are in poor condition, toxic, and wasted. In most cases of simple posterior basal empyema it is quite unnecessary, but it should be borne in mind in every case of total empyema or of empyema complicated by multilocular cavities, in which it offers prompt relief to what can otherwise be a long and disabling illness.

PARIS CLINICAL ASSEMBLY

A three-day meeting under the auspices of the Faculty of Medicine of Paris was held recently at the Hôpital Broussais to discuss recent developments in medicine. In addition to a large attendance of French doctors, visitors were present from Great Britain, Belgium, Holland, Switzerland, and Czechoslovakia. It was stated to be an occasion for the resumption by French medicine of its traditional role in the diffusion of medical knowledge. The sessions were presided over by, among others, M. Leveque, Director-General of Public Assistance, M. Duhamel, of the French Academy, M. Marx, representative of the Service of Cultural Relations of the Ministry of Foreign Affairs, and M. Paul Rivet, representing the Municipal Council of Paris. The expositors were, in the main, members of the Paris Faculty. At the first session problems of endocrinology were discussed, especially in relation to the female generative organs, also the value of synthetic oestrogens and of subcutaneous hormonal implants. After this came an exposition of recent work on hyperthyroidism and the favourable results obtained on the thyroid of recent synthetic products. The extension of knowledge concerning vitamins was also discussed, and the session ended with a survey of the refinements to which the radiological diagnosis of gastric carcinoma can now be carried. The second day was devoted to renal physiology and pathology, the indications for nephrectomy in states of arterial hypertension arising from a unilateral urinary lesion; and the study of the function of the liver, with the effect of benign or malignant hepatitis, without cirrhosis, in causing a generalized oedema. The third day was largely taken up with a discussion of the value of arsenical compounds and of the sulphonamides in the treatment of syphilis. Penicillin also came under review, and some warnings were issued against excessive enthusiasm. A demonstration was given of the success of skin grafting in extensive third degree burns, in which the healing process was aided by penicillin or the sulphonamides. The important discovery of the Rh factor in the blood was the subject of a further exposition. Electrocardiographic technique and modern methods of dealing with the psychoses were also on the programme. Dr. Pasteur Valléry-Radot, professor of clinical medicine of the Paris Faculty, who was largely responsible for the gathering, summed up the results of the three days' deliberations.

PSYCHIATRIC CASES REFERRED BY AFTER-CARE OFFICERS IN REGION 7

BY

FRANK BODMAN, M.D.

Consultant Psychiatrist, Somerset County Council

130,312 Army cases diagnosed as neurosis or psychopathic personality 26,275 were discharged to civil life, as against 445 out of 7,925 psychotics (Rees, 1945). Another 100,000 neurotics are in process of demobilization. What is their after-history?

In the last two years 20 ex-Service men and women have been referred to me by the after-care scheme organized by the provisional National Council for Mental Health in conjunction with the Board of Control. These patients, of course, represent only a small number of the total cases dealt with by the regional after-care officer, and are a mere fraction of the number of cases referred for psychiatric advice to other psychiatrists. But some common features which seem worthy of consideration emerge when the group is studied as a whole.

The personnel referred can be classified on the basis of their illness into four categories—organic nervous disease, psychosis, neurosis, and psychopathic personalities.

Organic Nervous Disease: Psychotics

There was one organic case—that of a man of 39 who was epileptic. The need for further advice in his case, however, arose out of a complex of social factors.

Five of the patients were psychotic cases. The disposal of these cases from the Army seems to depend on a decision of their relatives. They may be sent to a civilian mental hospital or be discharged to the care of their relatives. Brig. Rees (1945) gives the following figures for disposal of psychotic service men from the Army:

To Duty	To Civil Life	To Care of Relatives	To Civil Mental Hospitals	To Other Hospitals	Died
7.4%	26.9%	38.5%	7.5%	15.0%	4.7%

It is to be expected that a number of these patients, the majority of whom are discharged to the care of their relatives, should turn out to be a greater responsibility than their families could tackle.

Psychotic Cases

	Age	Illness	Disposal
R.A.A.F.	25	Depression	Voluntary patient civilian mental hospital
Private	31	Schizophrenic	Left home town
R.A.F. cadet	23	Paranoia	Certified
Private	30	Paranoia	Unemployed
Runner	29	Depression	Mental hospital

Among this group was a single man aged 31, a former teacher at a preparatory boys' school, whose case was diagnosed as a simple schizophrenia with a recommendation for prolonged analysis on discharge. This man attended for nine psychiatric sessions, but became progressively more inaccessible, and finally left his sister's house to stay with relatives at the other end of the country. It was recommended that he should enter a mental hospital as a voluntary patient.

Another single man, aged 23, an ex-R.A.F. cadet, was sent home from his training-school. He quarrelled with his family, developed ideas of reference, behaved in a bizarre fashion at his place of work, abandoned his lodgings, and took to sleeping out in sheds. He was reported to the relieving officer, admitted to the observation ward, certified, and placed in a mental hospital. He suddenly burst into my consulting-room one afternoon, dishevelled and bleeding, having escaped from the hospital over a wall topped with bottle glass.

A W.A.A.F., aged 25, joined the Services in an attempt to break off a homosexual attachment. Her self-imposed cure was unsuccessful, and she attempted suicide on one occasion by throwing herself in the way of an aircraft taking off. After a stay in a convalescent home, excellent lodgings were found for her, and she started work. But she failed to make progress, and was admitted to a general hospital in a very excited condition. A course of continuous sedation relieved her, but she failed to settle down at work on discharge

from hospital, and at her request was admitted to a mental hospital as a voluntary patient.

A man who was a misfit in his previous occupation found service in the Army a partial solution to his difficulties, but on his discharge could not bring himself to face returning to his old post. In spite of the greatest consideration by his employers, he developed an elaborate system of ideas of reference and persecution. Certification will probably be necessary.

Psychopathic Personalities

There were 3 patients who could be classified under this heading.

One was a young man, aged 22, who, after failing to gain the school certificate three times at his public school, volunteered for the Fleet Air Arm and failed twice in navigation. He joined the R.A.F., was selected as a cadet; but again failed twice in navigation. He tried to join the Army with the idea of obtaining a commission, but was advised against this. He then tried to join the Royal Navy, still hoping for a commission. On his discharge from the Services he applied for a grant for training in medicine. His attitude was completely egotistical, and each effort was concerned with his own social promotion—a fact which he admitted quite openly.

Another man, aged 26, an only boy of elderly parents, had noticed his homosexual tendencies before joining the Army. Life in the Services exaggerated his conflict, and he was discharged. Though of good physique, he abandoned jobs found for him by the Labour Exchange which involved some physical exertion, and was placed as an assistant in a draper's shop.

Another man, aged 22, had six jobs after leaving his private school; he joined the R.A.S.C., and staged an accident when in France in order to get back to England. He boasted to me of his successful malingering. While still in the Army he married a girl against her parents' wishes. Since his discharge from the Army he has had six different jobs. He has shown no consideration for his wife, knocks her about, and grumbles at the struggle involved in providing for his baby.

Neurotics

The remaining 10 subjects can be classified as neurotics. Eight of them had entered the Services with severe conflicts unresolved. Of the remaining two, one had broken down after severe combat experience, and the other was severely disturbed by his failure to obtain a pension. Their conflicts had been chiefly based on the usual adolescent problem of detaching oneself from the home, adjusting to the opposite sex, and finding a satisfactory outlet in work. In several cases all three main problems were involved.

Only one case appeared to be precipitated by combat stress. This was that of a naval rating who had an alarming experience when he fell between two ships and was in danger of being crushed. Subsequently, at the invasion of Sicily, he was serving on a battleship in a position high up on the superstructure, and saw his friends serving in an A.A. battery below him killed by a bomb from an enemy aircraft. He was discharged from the Navy and returned to his job as cinema operator. But in the projection chamber, high above the audience, he was in a similar position to that in the traumatic episode, particularly when the sound track was reproducing noises of gunfire and bombs, and it was not surprising that under these conditions he broke down again.

The man who suffered from a "compensation neurosis" was a sergeant in the paratroops who had joined the Army from an orphanage at 15 and had been transferred to the paratroops. He made one drop with a faulty parachute, and fell 500 feet into a ploughed field, landing on the buttocks. He developed a severe rectal haemorrhage, and was subsequently operated on for what was described as a rectal polyp. The operation left him with a discharging fistula. At the Pensions Board, "attributability" was denied, and his appeal was dismissed. He was very resentful about what he naturally considered a raw deal.

Of the remaining 8 subjects, 3 had joined the Services, driven unconsciously to satisfy their underlying conflicts.

One, an officer in the R.A.F., was afraid his father would put him into the family business when he left his public school. A casual encounter with a squadron leader took him to the Air Ministry, where he applied for training. He enjoyed the life in the Service, and, as he put it, if he could not fly there was no sense in living. He rarely went home on leave, and was miserable when "grounded." He developed psychosomatic symptoms, tried to mask these by heavy drinking, and was eventually discharged after an interview with a psychiatrist. Since his discharge he has turned down 117 jobs, and still sees no way of coping with reality except by "flying" away from it.

Another man, aged 25, the only earnest and conscientious member of an easy-going, happy-go-lucky family, deliberately joined the

Infantry in order to test himself out. The rest of his family managed to stay civilians as reserved men and women. But by the fortunes of posting in the Army he time and again missed actual combat service, and his repeated frustration and disappointment resulted in an anxiety state. Since his discharge he has become engaged, but evidently regards this as another test situation.

Finally in this group, a trooper, aged 32, was forced into trade by his father when he left school. He always had an urge to go abroad and travel, but was rejected when he tried to enlist in the Navy. He had a breakdown after his parents had interfered with his friendship with a girl, and joined the Merchant Navy. After a year he returned home, but found it hard to settle down. He volunteered for the Army, and would have liked to go over-seas, but was retained in England as an instructor. Once more he tried to get away over-seas, by volunteering for the N.A.A.F.I., and when this was refused he developed effort syndrome and was given a job as a civilian in the N.A.A.F.I. Here he felt "cooped up," and tried to rejoin the Army or the Merchant Navy to get abroad once more. He was successful in being retransferred to the Army, but six months later was no happier, as he was still in England.

Another group of neurotics was illustrated by 3 young men, who were emotionally and socially immature when they were called up, and on discharge from the Service found themselves unprepared to make any choice or decisions in civilian life.

An aircraftsman, aged 21, had been called up from the University. The medical board failed to notice his stammer, and he was posted to radiolocation in Northern Ireland. After vegetating there for more than a year he found his stammer had disappeared, and applied for a commission. He in due course had instructions to report in London, and set off cheerfully, believing he had been accepted as a cadet, to find, when he arrived in town, that he had been posted to a course in Japanese. The stammer quickly reappeared, and he was discharged. He returned home to his widowed mother, quite unable to make up his mind what to do. The mother treated him as a little boy, resumed her training in his table manners, and found him a job as a filing clerk. Analytical treatment of the stammer uncovered a series of episodes of "transvestism." When these had been discussed and dealt with he decided to read for a degree in commerce at the University, and applied himself with enthusiasm to the job.

Another aircraftsman, aged 26, had gone round with a gang when a boy. He was living at home with elderly parents when called up, was posted to the Bahamas, where he had little to do, and became very lonely. Faced with this limitation in his own resources, he became depressed, and subsequent transfer to California, where there was plenty of social life, failed to improve him. On discharge from the R.A.F. he returned home, but could not pick up old friendships, and felt that English girls treated him as an inferior. Unable to cope with English post-war civilian life, he has a vague wish to return to the U.S.A.

A mechanic from the Fleet Air Arm, aged 21, had been brought up in a Devonshire village, and was well adjusted at school, being on easy terms with both boys and girls before the war. When he left school his father found him a job in a garage just before the father was called up as a reservist. But he got on badly with his employer; he wanted "to get away," and applied for training in a Government Training Centre. City life confused and upset him, and when his course was completed he took the first job offered him in a different town, but was soon up against the landlady, who he felt favoured the other lodger. He was called up, refusing to use the reservation to which he was entitled, but in the training camp became depressed, spent some months in a Naval hospital, and found himself once more on another civilian training course. He was so used to being "parked around," as he called it, that he found himself unable to make any decisions about a job when his course was finished.

Summary

Although the majority of Service psychotics were discharged to the care of their relatives, very few of them could be managed successfully at home. In the majority of cases after-care should be directed to persuasion to enter mental hospitals as voluntary patients.

All three psychopaths were ready to avail themselves of the after-care service, but were using it as a screen to avoid further social responsibilities. It is doubtful whether an overloaded service should attempt to deal with this category.

The group of neurotics, all volunteers, had used the Services as an escape mechanism from adult responsibilities. When discharged they found themselves faced with the original unsolved problems, and all wished they were back in the Services. One succeeded in rejoining. Resettlement is unlikely to be successful in such cases without prolonged individual treatment.

Another group of neurotics are those young men who were socially and emotionally immature when called up. Service life relieved them from the need for making choices and decisions. On discharge at

ages ranging from 21 to 25 they are still fixed at emotional levels of 14 to 15, and are unprepared for individual independence. Some form of group therapy and training would seem to be indicated for these, and their relatives need advice as to their necessity for further support and encouragement.

Combat neuroses are comparatively infrequent—a tribute to the prompt measures of dealing with these cases in the Services.

"Compensation neuroses," based on decisions of pensions boards naturally occur. There are bound to be "hard cases," but the impression received is that more time spent in explanation of the decisions by trained personnel would prevent a great deal of unavoidable resentment and subsequent maladjustment.

There is a grave lack of out-patient facilities for treatment, as distinct from diagnosis, of these neurotic persons. Many of these men were seen in private time, without charge, as no out-patient time was available for them.

I am grateful to Dr. Rees Thomas, of the Board of Control, for permission to publish, and to Miss Evelyn Fox, C.B.E., for her kind interest. I wish to thank Miss Howarth, Regional After-care Officer, Region 7, for her invaluable help in the social work.

Rees, J. R. (1945): *The Shaping of Psychiatry by War*, London.

SCOTTISH EMERGENCY HOSPITALS SECRETARY OF STATE'S DECISION

The Emergency hospitals in Scotland built by the Government to deal with wartime needs are to continue to be administered by the Department of Health until the National Health Service is set up. These needs now require only a part of the resource available, and the balance will be available for general hospital purposes. Announcing this decision, the Department state that "while the Secretary of State's obligations under the scheme cannot be discharged at present without substantial reservation of beds in local authority and voluntary hospitals, he is anxious to reduce these reservations to a minimum and as far as possible to restore complete freedom to hospital authorities in the selection of patients to be admitted." Voluntary hospitals may continue to arrange for the admission of patients from their waiting list to the Department's own hospitals, whose resource will also be used as at present to help local authorities to offset their statutory responsibility for tuberculous and orthopaedic cases.

The Emergency Hospital Scheme was created and developed under powers contained in the Civil Defence Act, 1939, which places on the Secretary of State the responsibility for ensuring that facilities would be available for the hospital treatment of casualties occurring in this country from enemy attack. The scope of the scheme was progressively widened to cover the treatment of Service personnel, marine casualties, evacuated persons, workers in war industry suffering from fractures, transferred war workers, and other classes.

To meet the additional needs a substantial building programme had to be undertaken. Several new general hospitals with over 4,000 beds on a peacetime standard were built and are under the direct management of the Department of Health. In determining the sites of the new hospitals attention was paid both to strategic considerations and to probable post-war requirements. 24 hospitals were extended by the erection of new annexes varying from two ward huts (60 beds) to 40-ward huts (1,200 beds). Purely temporary accommodation was also obtained by various means, including the use of 60 large private houses as convalescent or auxiliary hospitals.

In addition to the new hospitals and the hospitals at which annexes were built, the Emergency Hospital Scheme embraces almost all Scotland's voluntary hospitals—including cottage hospitals—and a large proportion of the local authority hospitals in Scotland. These hospitals were required to keep a proportion of their beds always vacant to receive casualties or other persons entitled to treatment under the scheme. The Government made a payment to the hospital authority both for beds occupied by patients falling within the scheme and for unoccupied beds kept vacant. Thus the large bulk of the hospitals in Scotland have been linked up during the war years in a single comprehensive service under the general control of a central authority.

Special units of various types were set up in 17 hospitals, for orthopaedic work, plastic surgery, brain surgery, and many other types of specialized treatment. The units were equipped with up-to-date apparatus, and arrangements were made for the services of eminent surgeons and other specialists. Where these special units were located in the new hospitals they will now be continued for the benefit of the civilian population. The largest of these hospitals are at Stracathro, Angus; Bridge of Earn, Perthshire; Law, Lanarkshire; and Ballochmyle, Ayrshire. Others are at Killearn and Raigmore near Inverness.

Reports of Societies

BRITISH ORTHOPAEDIC ASSOCIATION

The spring meeting of the British Orthopaedic Association was held at the Royal Victoria Infirmary, Newcastle-upon-Tyne, on May 24 and 25, under the presidency of Mr. George Perkins.

Mr. E. A. NICOLL reported upon 150 miners who had suffered fractures of the thoracic or lumbar spine, which he classified into (a) simple anterior wedge, (b) lateral marginal fracture (whose special features he defined), (c) fracture-dislocation, and (d) fracture of the neural arch. The results of simple wedge fracture did not depend necessarily upon the presence or absence of deformity. Hyperextension treatment would not promote repair of a concomitant intervertebral disk injury and was often self a source of chronic lumbar strain; consequently he now referred early exercises with no more restraint than bed rest.

Mr. J. K. STANGER dealt with cases of fracture-dislocation of the spine, which occurred mostly in the thoraco-lumbar and mid-cervical regions. Paraplegia was commonest with injuries to the narrowest parts. Recoverable cases of paraplegia could not be distinguished from irrecoverable, and hence reduction could be attempted. In open reduction of cases with locked facets partial facetectomy was rarely needed; and exposure might even reveal that spontaneous reduction had begun, only hyperextension being required for its completion. Although the results of open reduction in these cases with locked facets and paraplegia were exceedingly disappointing, and although closed reduction could be achieved, Mr. Stanger did not yet feel able to advocate the latter as the usual procedure. Fixation was by plaster jacket, or by plaster bed if posterior structures were fractured. Redislocation, which was frequent, did not cause recurrence of cord symptoms and was often followed by bony ankylosis. The first evidence of recovery from paraplegia might appear as late as six weeks after the injury, and the extent of delay was no measure of the prognosis. Patients with various degrees of recovery after paraplegia from fracture-dislocation were shown.

Mr. W. GRANT WAUGH gave a restrained account of his researches into the pH of acute and chronic joint effusions, and of his attempts to modify this by the injection of appropriate liquids. A clinical estimate was given of the results of treating the joints in osteoarthritis and rheumatoid arthritis by intra-articular injections of a solution of lactic acid and procaine of approximately constant pH. The injections were followed by exercises, and later manipulations, which were facilitated by the injections and formed an integral part of the treatment. Procaine solutions were not a satisfactory substitute. Mr. Waugh asked for trial of the method by others. Some present were able to report encouraging results.

Mr. K. H. PRIDIE advocated excision of the calcaneus in very severe cases of comminution and showed film strips to demonstrate the supple feet, good gait, and powerful plantar flexion power which might follow this procedure if continuity of tendo Achillis and plantar fascia was maintained. He considered that the subcutaneous fibro-fatty pad and the partially regenerated bone provided a serviceable heel. In the lively discussion which followed, the consensus was in agreement with Mr. Pridie's condemnation (following Eastwood) of immobilization of these fractures, strong in advocacy of early movement without weight bearing, but condemnatory of so drastic an operation, and particularly its performance, through a longitudinal dorso-plantar incision.

Mr. E. W. KNOWLES had found that mid-tarsal dislocation might follow either a fall from a height or a torsion injury such as that resulting from a fall with the forefoot trapped. Reduction was very insecure. Consequently he advocated transfixion of the joint with a Kirschner wire passed through scaphoid and talus and incorporated in plaster-of-Paris for four weeks.

Mr. J. B. REID had investigated the results of McMurray's displacement osteotomy of the femur in osteoarthritis of the hip and in ununited fracture of the femoral neck. Of 36 patients with osteoarthritis, 28 were completely relieved of pain. Among 13 patients with ununited fractures, union followed in 7, and one patient died.

Mr. P. H. NEWMAN, M.C., discussed the clinical diagnosis of fat embolism, which had been frequent in war injuries and, if sought, would probably be found to be correspondingly frequent in civil life. Mention was made of the psychological changes, pyrexia, tachycardia, increased respiratory rate, raised blood pressure, petechiae of characteristic distribution, fundus-changes, presence of fat in the last-voided urine, and the lack of information given by the sputum. The importance of efficient splinting and transport of patients with fractures was stressed. Mr. Newman had ligated the deep femoral vein in two cases, one of which had recovered.

Mr. A. GRAHAM APLEY gave a preliminary demonstration of a test designed to aid discrimination between meniscal or other soft tissue injuries of the knee. Clinical cases shown included unilateral adolescent coxa vara (slipped upper femoral epiphysis) in father and each of twin sons (Mr. C. GORDON IRWIN), tendon transplantations (Mr. J. GILMOUR and Mr. DAVID BROWN), melorheostosis, osteoid osteoma (Dr. W. MACKENZIE), and some results of nerve suture (Mr. F. G. ST. CLAIR STRANGE).

Mr. JOHN GULL demonstrated an ingenious invalid armchair which would hoist the patient on to his legs in an upright position or conversely lower him gently into the sitting position, the power being provided by an electric motor.

SPREAD OF INFLUENZA

Opening a discussion on June 28 at the Royal Society Empire Scientific Conference at Cambridge on the spread of influenza, Dr. C. H. ANDREWES said that there were two apparently conflicting views as to the epidemiology of influenza, and both might be right.

According to one view, influenza always reached a country from somewhere else. Epidemics over here had thus been called the Russian or the Spanish or some other kind of influenza according to their supposed place of origin. Outbreaks in Britain usually lasted for at most three months, and virus A—the more important of the two known influenza viruses—might not be recognized at all in this country for the twenty-one months or so before another outbreak occurred. Was its normal existence a progression round the world, producing epidemics, passing from the northern to the southern hemisphere and back again according to season? Recorded data as to the periodicity of influenza in different parts of the world did not support such a view. Epidemics in Britain, on the European continent, and in North America tended to appear at about the same time, but there had been no discernible regular relation to those in the southern hemisphere.

The second view supposed that the influenza viruses were always with us, perhaps in the respiratory tracts of some people who were carriers, perhaps causing, between epidemics, sub-clinical infections or sporadic respiratory ailments. Then, after the lapse of time, the immunity of the population waned to a suitably low level, and some climatic or other as yet undefined factor set the stage for a greater or lesser outbreak. An argument for such a view was the occurrence, as in Britain in 1937, of a number of antigenically distinct variants of influenza virus A, all in one outbreak. There were, too, a number of examples on record in which viruses A and B had turned up in one and the same epidemic. Shope had made out a very strong case for believing in the genesis of an outbreak of swine influenza by simultaneous activation of latent virus in a number of separate droves of pigs.

Behaviour of B Virus

Dr. Andrewes said that he was practically convinced of the truth of this latter view of the endogenous origin of human influenza epidemics until virus B began causing trouble in June, 1945, in Hawaii and Guam. Thereafter it spread East, and epidemics—all mild ones—appeared in the next few months in the Caribbean area, the more northern parts of S. America, and in Texas. Thence a rather slower spread occurred in the U.S.A., but B was widely prevalent in that country by November. In Europe it did not appear till December, in Holland and Belgium; the peak in Britain was in January. From the Pacific the virus apparently went also southwards and caused an outbreak in Australia at what was for them an unusual time of year—November. There were two reasons for believing that

there was a true spread over the world. First, B strains recovered recently in Australia and Britain were antigenically very closely related and decidedly different from the standard B strain Lee isolated in America in 1940. Second, the disease showed rather unusual epidemiological features, and those which Burnet had described from Australia were identical with those seen lately in this country. In both countries the incidence had been very patchy, but with a high incidence in school-children and very little in adults, noticeably little in the Army. Dr. Andrewes wondered, therefore, whether the influenza viruses might not be endemic in every country, but at the same time so labile that they easily produced mutant forms sufficiently distinct antigenically from the stock to be able to infect a substantial number of people who were resistant to their endemic strain. Virulence might soon be raised and further extension made possible. Thus a country-to-country spread could be quite commonly superimposed upon endemic influenza. What had perhaps occurred during the past year with virus B might be not unlike the happenings of 1918-19, except that in contrast to the pandemic virus last year's antigenic variant of B caused only a mild disease, not readily differentiated from the local endemic influenzas.

It would not be possible to find out whether there was a country-to-country spread as a normal occurrence unless there was co-operation between countries in collecting and comparing strains from outbreaks. In every considerable region within the Empire there should be trained observers capable of collecting and comparing strains, or at least collecting and transmitting to centres where detailed comparisons might be made. The global epidemiology of influenza might be in a state of transition as a result of the enormous increase in air transport. If so, it was most important to be able to observe accurately what was happening.

Correspondence

The Hypochondriac's Treatment

SIR,—Dr. Edith Summerskill has told us that "In future no doctor need prostitute his science by pandering to the hypochondriac." Dr. Alfred Cox in his letter to the *Times* (June 14) writes: "I would rather see them making concessions to patients who mistakenly think they are ill, than being bound by the regulations which are intended gradually to make the doctor into a Civil Servant whose primary duty is not to his patient, but to his employers." Dr. Lindsey Batten (June 29, p. 999) assumes that the doctor is more free than he would be in a State Medical Service to discard the hypochondriac.

None of these authorities differentiates between the treatment of the hypochondriac's complaints and the treatment of his hypochondria. They all assume that the hypochondriac is incurable, and that the only treatment available is the treatment of his alleged symptoms. This assumption is inadmissible unless a serious approach along psychological lines has been attempted and failed.

But this out-of-date assumption is implicit in the teaching of the medical schools. Students learn "not to waste time" on the hypochondriac's symptoms; this is an excellent precept but it gets us nowhere. The hypochondriac is not a conscious delinquent to be ousted from the sphere of medical treatment and professional sympathy. He is a victim of fears he does not understand; his symptomatic figments are the result of conflicts in his personality; he is even more exasperating to himself than he is to his doctor; he needs treatment badly, even when his alleged symptoms are fatuous.

Will Dr. Summerskill tell us who is to teach the next generation of doctors the science—and art—of treating the hypochondria of the hypochondriac?—I am, etc.,

Harrow-on-the-Hill.

H. CRICHTON-MILLER.

Psychology in the Child's Education

SIR,—One cannot but agree with Dr. D. W. Winnicott's forthright letter (June 29, p. 998) on the integrity of the home, and on the principle of rendering to Caesar the things that are Caesar's. But his statement on keeping children sad when they

are in hospital by allowing their parents to visit them surely calls for strong evidence.

My best psychiatric social worker, a lady of some erudition and personal charm, gave me two papers to read written by London-psychiatrists. She did so, obviously feeling sorry for me, in order to draw my attention to the dangers of "hospitalization." Both authors quoted at length case histories of neurotic children associated with separation of the mother: an early age for hospital purposes. But no controls were described. In argument against these papers the hospital histories of hundreds of people without gross neurosis are in existence.

I do not think there is any doubt that serious cases of psychiatric trauma occur in some young children going to hospital. But is not the damage done at the time of separation? Is the separation not in most cases mishandled by anxious mother or too businesslike nurses? Should nurses not have more training on this particular point? Should the mother not receive some few minutes' coaching on how to behave when the child is leaving?

The emotional disturbance of visiting-hours which occurs in some children's wards is obvious evidence that the separation has done damage, and those physicians and surgeons who frown on parental visits are on good psychiatric ground. I would like to agree with my psychiatric social worker on her point, but until the separation of the child from its mother is more skilfully handled along tactful psychiatric lines, I would deplore the necessity of re-enacting the psychic trauma by having parental ward visits which could be avoided. Much more would I avoid deliberately "keeping them sad."—I am, etc.,

Surrey.

JOHN A. McCLUSKIE.

SIR,—It is quite likely to be useful if doctors will give the ideas about education in its wider sense—i.e., as an education for life, because they see an aspect of life which is not accessible to the general public or to teachers. They see people during periods of emotional stress, and consequently know a side which is not usually thrown into relief. In my opinion they should confine themselves to this, for when they begin to put forward views on the curriculum they are in danger of falling into the trap of telling teachers what they already know very well. Let us therefore leave teachers to their own job and try to give them our knowledge about living people. Such knowledge can only enrich their work.

When one comes to the subject of citizenship doctors can give something, for citizens are living people, whom we know at their best and at their worst. We know something about where they triumph over adversity or fail in their citizenship. One thing stands out: we can say, and this should by now be known, that becoming a citizen is not a matter of words but a question of behaviour. Consequently we can tell teachers that it is useless to talk on the subject unless they themselves are good citizens, whatever that may mean. We can also tell them that if they are good citizens it is only of secondary importance what they say to children.

The same kind of argument applies to teaching psychology. I myself feel confident that children would like to hear adults talking about psychology—in fact I know they do—and the deeper the better, because it is near what they experience. But we should, however, not expect that this will make them any better people. Psychology is essentially a two-way affair. To be effective in education it must express something the teacher knows and applies in his actual life, otherwise it is just hot air.

In conclusion I must return to my doubts about teaching the teachers, especially since they really do know quite a lot about children, indeed much more than most doctors. We know that our profession itself is in urgent need of education about handling children. Let us beware, therefore, that in setting ourselves up as authorities in the realm of another profession we do not lay ourselves open to the reproach of "living in glass houses."—I am, etc.,

London, N.W.1.

MICHAEL FORDHAM.

Gas Gangrene of the Gall-bladder

SIR,—Mr. W. R. S. Hutchinson in his article on gas gangrene of the gall-bladder (June 15, p. 915) quotes seven cases from the literature and adds an eighth, but he does not attempt to explain the rarity of this infection in cholecystitis. MacLennan was in the same quandary when he posed the question: "Wh

DIGOXIN 'B. W. & CO.'

The dosage of Digoxin 'B. W. & Co.' is computed in *milligrammes*, not units. Being a single pure glycoside of constant composition and activity, Digoxin 'B. W. & Co.' offers an unsurpassed degree of precision in digitalis therapy. Its rapidity of absorption and excretion, and the fact that it can be injected intravenously if necessary, are additional features of high importance.

PENICILLIN

(Local therapy)

Local application of penicillin by means of lozenges has a special value in the treatment of most of the common streptococcal infections of the mouth, throat and pharynx. The lozenges are also particularly effective against Vincent's infections of the mouth and gums; pain is relieved within a few hours, accompanied by clinical improvement. The period of infectivity after scarlet fever can also be reduced by their use. The average dose consists of 6-20 lozenges.

PENICILLIN LOZENGES B.P.

Each lozenge contains 500 units of calcium penicillin
Bottles of 50 and 500

PENICILLIN Glaxo. Dry sodium salt for injection in aqueous solution. Vials of 100,000; 200,000; 500,000; and 1,000,000 (1 mega) units.

OILY INJECTION OF PENICILLIN B.P. For intramuscular injection. 125,000 units per cc. of calcium salt in oil and beeswax. 10 cc. vials.

IN INFANT FEEDING

THE wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In cases of under-nourishment, functional or otherwise, it is reasonable to give the infant the kind of nourishment which will necessitate the least effort, and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional requirements of conditions requiring acid milk feeding, the following range of products is available.

LACIDAC SEPARATED
Almost fat-free. Suitable for temporary feeding of infants incapable of tolerating fat.

LACIDAC HALF CREAM
An intermediate grade for less severe cases and for graduation to normal feeding.

LACIDAC FULL CREAM
Suitable for long term use or as a final stage of graduation to normal feeding.

PROLAC

Of approximately half cream fat standard but with increased protein as required in gastro-enteritis, etc.

Rationing and the adolescent

Some of the rising generation are undoubtedly having a "thin time." Those who get no extra midday meal at work or school are particularly dependent upon expert home catering and their health may benefit by occasional supplements.

When treating cases of debility, anaemia, etc., in which sub-optimal nutrition is regarded as a contributory cause, Complevite Tablets will be found a convenient, acceptable and economical method of supplying the most important vitamins and minerals.

As the table shows, Complevite is a balanced supplement designed to make good the known deficiencies of the average diet

Average Dietary Deficiency	Therecommended adult daily dose of Complevite supplies
1700 I.U.	VITAMIN A 4000 I.U.
150 I.U.	VITAMIN B ₁ 200 I.U.
350 I.U.	VITAMIN C 400 I.U.
250 I.U.	VITAMIN D 300 I.U.
0.15 g.	CALCIUM 0.15 g.
0.002 g.	IRON (as ferrous sulphate) 0.002 g.
0.15 g.	PHOSPHORUS 0.15 g.
	TRACE MINERALS

*The iron in Complevite exceeds the calculated deficiency expressly to combat the nutritional anaemia so common in children and in women of child-bearing age.

COMPLEVITE

TRADE MARK 'AMYTAL' BRAND
ISO-AMYL ETHYL BARBITURIC ACID

For Simple Insomnia

For simple insomnia caused by physical or mental strain, fatigue, or worry, 'Amytal' supplies the necessary relaxation and sleep. Upon awakening the head is clear; there is no after depression; energy and self-confidence are restored.

'Amytal' is supplied in $\frac{1}{4}$ grain, $\frac{1}{2}$ grain, and $1\frac{1}{2}$ grain tablets.

ELI LILLY & COMPANY LTD.

BASINGSTOKE AND LONDON

it that only 1% of war wounds infected with clostridia develop gas gangrene?" Quoting Gordon-Taylor and Whitby, Jr. Hutchinson shows that *Cl. welchii* are found in 1 out of very 11 cases of cholecystitis. It would be a grotesque misapprehension to assume that gas gangrene occurs in this proportion of cases. It is not strange, then, that some other cause must be found for the infrequency of this infection.

I have reported 16 cases of gas gangrene in war wounds May 12, 1945, p. 656) and showed that clostridia could not flourish on healthy muscle, and that ischaemic or necrotic muscle was essential for the establishment of gas gangrene resulting from arterial damage or occlusion. I believe that gas gangrene of the gall-bladder can only occur when this organ is partly or wholly deprived of its blood supply. This is obviously a rare occurrence and can only be accounted for by pressure on the cystic artery, the most likely cause of which is inflammatory oedema, especially when stones are impacted in the cystic duct. An abnormal position of the cystic artery may also be a predisposing cause. If the artery is partly occluded, it is the fundus of the gall-bladder which first becomes ischaemic, as apparently happened in this case. Should the artery be totally occluded the whole organ becomes necrotic. Once the gall-bladder is removed (as when all ischaemic or necrotic muscle is removed in war wounds) there is no cause for anxiety: gas gangrene cannot develop in the healthy muscles of the abdominal wall.

Mr. Hutchinson's statement that "Fulminating gas gangrene of the liver, following cholecystectomy, occasionally provides an unwelcome reminder of their presence" has a distinct bearing on my hypothesis. I believe it can only result from ligation or injury to the hepatic artery at the time of operation, for primary gas gangrene of the liver is otherwise unknown. Clostridia are ubiquitous. They are in our clothes, on our skin, in our air-passages and alimentary tract. They are ever in search of ischaemic or necrotic tissue, and it is only when this is forthcoming that they can do us any harm.—I am, etc.,

Hereford.

R. WOOD POWER.

Jittery Legs and Burning Feet

SIR,—Dr. K. P. Hare (June 22, p. 968) appears to be interested to know when the term "burning feet" was introduced. I used the phrase first in 1911, but Strachan mentioned "burning pains in the palms and soles" in 1888 when describing a condition he called malarial peripheral neuritis, but which I later brought evidence to show was a deficiency state. Long before this, however, in 1825, a paper was read in Calcutta by J. Grierson, Esq., attached to the Arracan division of the Army, "On the Burning Feet of Natives," and the term was probably in common use even earlier.

In 1936 I collected together a number of descriptions of the affection, and in 1942 suggested that the symptom might form part of a larger neurological syndrome due to a deficiency of riboflavin and/or some closely associated factor. The work of C. Gopalan would now appear to show this to be folic acid.—I am, etc.,

London, W.1.

HUGH S. STANNUS.

Black Tongue and Oral Penicillin

SIR,—With the release of penicillin for sale by pharmacists on medical and dental prescriptions, its administration will become general. I venture to predict that one of its most common uses in general practice will be in the treatment of sepsis of mouth and throat by means of lozenges and sprays. I have personally observed melanoglossia in two instances as a concomitant of such treatment, and, having heard of a third from a colleague, infer that the condition will be seen with increasing frequency. This letter is written in order to apprise those who have not yet administered penicillin as oral lozenges or throat spray of a complication of treatment which, though innocuous in itself, may occasion alarm. It is hoped that bacteriological investigation of a sufficient number of these cases will elucidate the cause of this puzzling condition.

Case 1.—A previously healthy male aged 28 reported with sore throat, hoarseness, and slight malaise of two days' duration. He was a moderate smoker (10 a day), not subject to sore throats. T. 99° F. (37.2° C.), P. 78; teeth and gums healthy; tongue clean; oro- and nasopharynx injected; tonsils moderately enlarged; R. tonsil oozing pus from several crypts; tender R. tonsillar lymphadenitis;

no abnormality detected in other systems. Treatment: penicillin lozenges (gelatin base; 250 units per pastille), one to be inserted into the buccal sulcus and retained as long as possible; another to be inserted as soon as the first dissolved, and so on during the waking hours. The patient continued at work. He was advised not to smoke. No other treatment was given. *Second Day* (after 12 lozenges): T. 98.2° F. (36.8° C.), P. 72; subjectively much improved; tongue clean; tonsils settling, pus not expressible from either; lymph glands not tender. *Third Day* (after 9 more lozenges): Feels quite well; T. 97.8° F. (36.5° C.), P. 72; tongue lightly coated with yellowish fur; tonsils clean; R. tonsillar lymph gland palpable but not tender; oro- and naso-pharynx normal. Treatment discontinued: patient discharged cured. Total number of lozenges administered 21. *Fifth Day*: Reported with "black tongue." The tongue was covered on its dorsal surface with a dark-brown fur. The edges and tip were clean and normal. The coat was thickest posterior to the circumvallate papillae and in the median sulcus anteriorly; it faded towards the tip and edges. The colour was most intense, indeed quite black, where the coat was thickest—i.e., in the median sulcus and on the posterior surface; these places looked like worn black velvet, the "pile" being about 1/8 in. (3 mm.) in length. The edges of the coat were a dark brown, and the whole tongue had a moth-eaten, furry, velvety appearance. It was covered with a musby brown detritus which left a dark-brown speckled stain on gauze; its removal did not materially affect the appearance of the tongue. Apart from the tongue, there was no abnormality on examination. There was no malaise, no fetor, no unpleasant taste, and no dyspepsia. He admitted recommencing smoking yesterday. He denied the use of mouth-washes or the ingestion of coloured confections; he had not sucked Brompton or other liquorice lozenges; he had drunk strong tea, but this was his normal practice. He was reassured; no treatment was advised, and he was kept under observation. *6th to 10th Days*: No appreciable change. *11th to 16th Days*: Gradual thinning and disappearance of the fur from the lateral edges medially. The last area to clear was in the median furrow for about 2 cm. anterior and posterior to the circumvallate papillae. *18th Day*: The tongue presented a perfectly normal appearance. He had remained symptom-free throughout. He had never suffered from the condition before. There was no family history of melanoglossia.

Case 2.—Male aged 31; reported with sore throat and dry, irritating cough following a "cold in the head, which always goes to my chest" three days previously. T. 98.2° F. (36.8° C.), P. 72; oro- and nasopharynx injected, dry, and glazed; tonsils absent (removed at age 23); tongue, teeth, and gums normal; other systems revealed no abnormality. Treatment: penicillin pastilles as for Case 1 (gelatin base, 250 units per lozenge) and penicillin throat spray (250 units per ml.), inhaling deeply with each squeeze of the bulb, six squeezes half-hourly during the waking hours. No other treatment was given. He was advised not to smoke. All symptoms and signs had subsided after two days and treatment was discontinued (number of penicillin lozenges 19). Two days later (i.e., four days after commencing penicillin therapy) he reported with a heavily coated dark-brown tongue which, by the next day, was similar in every respect to that in Case 1. He had not smoked, gargled, nor used a mouth wash. He had sucked no coloured confection. He presented no sign of syphilis or other disease. There was no fetor, dyspepsia, or unpleasant taste, but he had suffered some embarrassment from facetious comments from his acquaintances. The condition remained *in statu quo ante* for five days and then rapidly regressed. Sixteen days after his first reporting, his tongue had regained normality.

There was no connexion either socially, geographically, or in type of employment between the two cases. Bacteriological investigation was not possible in either case, as laboratory facilities were not available. "Black tongue" receives scant mention in the standard medical textbooks. Dermatological reference books describe two types (true or idiopathic, and false or pseudo) of black tongue (syn.: melanoglossia, lingua nigra, black hairy tongue, hyperkeratosis linguae). Sutton (*Diseases of the Skin*, 1931) considers the condition a rarity and states that only 50 authentic cases had been recorded since Rayer's original description in 1835. In discussion following a meeting of the Dermatological Section of the R.S.M. (*Brit. J. Derm. Syph.*, 1937, 49, 243) this view was questioned by Parkes Weber, who suggested that black tongue was seen not rarely in the out-patient departments of ordinary hospitals. The "true" black tongue is characterized (Sutton, 1931, Andrews, 1938) by well-defined, circumscribed, thick, stable, soft, fur-like, brown to black patches with filaments 1/4 to 1/2 in. (6 to 12 mm.) long on any part of the surface of the tongue but especially that area immediately anterior to the circumvallate papillae. The "false" is characterized by its instability, evanescence, its covering of soft mushy detritus, and its shorter length of filament. Andrews (*Diseases of the Skin*, 1938) includes

among the "pseudo" variety a "mycotic" type, and a photograph in his book exactly mirrors the condition of the two cases described above. Heidingsfeld (quoted by Sutton and Andrews) considers the condition to be a congenital abnormality developing in later life and attributes the colour to changes in the horny cells of the hypertrophied filiform papillae as in the dermal hyperkeratoses. Oppenheim (quoted by Andrews) produced hypertrophy and hyperkeratosis of the filiform papillae by painting with vegetable tinctures and compares the effect to that produced on the skin by tar and aniline products. Prinz (quoted by Andrews) ascribes the pigmentation of the elongated papillae to a deposit of pigment from external sources (a reaction between the haemoglobin of the blood and sulphur and ammonium compounds derived from protein debris or tobacco). The appearance in mycotic black tongue is said to be due to the filamentous mycelia of fungi growing as moulds on the dorsum (Andrews, 1938). Thompson and Montgomery isolated an actinomycete from two cases. Wiedman grew *Microsporon minutissimum* from a case. This worker (quoted by Sutton) connects black tongue with trichomycosis—i.e., suggests a symbiosis between the fungus *Nocardia tenuis* and a black-pigment-producing bacterium, *Micrococcus ingrescens* (Castellani, quoted by Sutton). The *Journal*, in answer to a question on the subject (1943, 2, 317) considered the black colour due to the fungus *Aspergillus niger*, but suggests that a yeast or a chromogenetic bacterium might be implicated. Among the exciting causes are listed tobacco, sulphenamides, atropho-neurosis, gastric hyperacidity, irritant mouth-washes, syphilis, antiseptics, astringents, and colouring matter introduced into the mouth.

The two cases described above were, I have very little doubt, of the "mycotic pseudo" variety, and, although they may have arisen fortuitously, the role played by penicillin is strongly suggestive of a cause-and-effect relationship. A likely aetiological view is that the fungal spores (and chromogenetic bacteria) are not uncommonly present in the air and mouth, but their growth is inhibited by the products of the normal buccal symbiotic flora. When penicillin alters this biological balance (cf. sulphaguanidine and streptomycin in the bowel) conditions then become less inimical to the growth of the organisms of "black tongue," which clinical condition may then arise. Such a theory would explain the "mycotic" cases unconnected with penicillin, the normal biological balance being disturbed by certain local irritants and antiseptics.—I am, etc.,

Leeds.

P. D. BEDFORD.

Notification of Venereal Disease

SIR,—Mr. C. M. Ockwell (June 15, p. 929), in urging the adoption of some system of notification of venereal disease, says: "The two chief types who are mainly concerned in the spread of venereal disease are: (1) defaulters; (2) the irresponsible professional and amateur." Is there not a third type? i.e., the persons by whom the "irresponsible" ones have been infected. Many people appear to believe that women and girls who lead promiscuous lives somehow originate V.D.! I do not suppose Mr. Ockwell to be one of these, but he does not seem fully to appreciate the fact that while men are of course infected by diseased women each of these women has been infected by a diseased man.

Every scheme for notification so far put forward has ignored some factor which must limit its possibility of success when put into practice. Mr. Ockwell, for instance, proposes penalties for anyone who "knowing that he is suffering from an infectious disease exposes other persons to the risk of infection." Even with universal notification—of private patients as well as of those attending clinics—there would still be enough people who could not be proved to have known that they had V.D. in an infectious form to make a considerable leakage.

Regarding defaulters from treatment, it must always be an open question whether the number of persons deterred from defaulting by the weapon in the background would equal the number deterred by it from ever coming to the clinic at all. It is obviously very misguided not to want to come and be treated, but Mr. Ockwell says such people "are mostly sub-normal or abnormal mentally or psychologically," so what can we expect? Not that I agree with his statement. Practical experience in social work shows how many reasons there are why regular attendance at a clinic for a long period is ex-

tremely difficult, involving, as it often does, much absence from work or from pressing home and family duties, and calling for exceptional qualities of perseverance and moral courage. More over there are two deeply ingrained common instincts. First the instinct to resist being driven by threats; secondly, unwillingness to undertake anything without seeing just what it may involve. To the question, "If I start this treatment have I got to follow it up?" the answer, "You'll be silly if you don't but no one can make you," is very often successful where "You'll be punished if you don't" would certainly fail.

The free confidential system of treating venereal disease was meeting with considerable success before the war. There seems no reason why with more education, more and better staffed and equipped clinics, and more social workers of the right kind with no whips up their sleeves, its future success should not be still greater. It must be gradual, and it is difficult not to be impatient, but apparent short cuts by way of penal legislation are likely to prove a much longer way round.—I am, etc.,

KATHARINE B. HARDWICK,

General Secretary,

Association for Moral and Social Hygiene.

London, S.W.1.

P.S.—Dr. S. M. Laird, in his letter (June 29), recommends that official action under Regulation 33b should be allowed to be taken on one notification. This step seems likely to increase both the number of persons deterred from seeking treatment, and the difficulties of the social workers who are now tracing once-named contacts for the clinics. These workers often attribute their success to the very fact that they come a friends with no authority to enforce their advice.

Medical Future of the Colonies

SIR,—The correspondence in your columns may benefit us in the Colonies little since the B.B.C. has announced the appearance of a White Paper which promises basic pay for Colonial civil servants irrespective of race and domicile. If this means equal pay for equally qualified African and European medical officers, as demanded by Dr. Thomas (April 27, p. 663) and others, then either (a) recruitment of Europeans will cease since none will come to the Colonies, or (b) Africans will be grossly overpaid. If the market value of a young medical man in Britain is £x per annum, then he must be granted £x plus some kind of "danger" or "expatriation" allowance to compensate him for all that living in, say, West Africa entails—separation from home and family, isolation from professional contact, a definite risk to health. The West African, enjoying some kind of immunity to the local diseases and living, perhaps, in his own home town, is to be given the same "danger" money and enjoy an income greater than his market value of £y per annum. No European will come to West Africa for the same salary as he can command at home. I can hardly imagine even a Colonial Financial Secretary approving a salary for an African greater than that he could obtain in Britain. For many years we in the Colonies have demanded basic salaries for holders of similar posts, but we must insist on the provision of expatriation allowance for non-native officials.

Dr. Thomas states that the schooling of our children left behind in Britain need cost us nothing. Having enjoyed an excellent free education and disliking the public school system I thoroughly agree, but the children must be fed, clothed, and housed. I know of no British education authority which provides these items free for men of professional standing. Moreover, the upkeep of European children in a temperate climate is rather more costly than the upkeep of African children attending the numerous excellent schools run by Government or State-aided missions in the larger coastal towns here; inclusive fees for board and tuition may be £25 to £50 p.a.; only light drill outer garments are necessary. Regarding higher university education, our African colleague is in a most favourable situation. In order to produce local graduates scholarship of up to £350 p.a., which may be increased to over £400, are offered to any African child who can pass a university entrance examination. Although we Europeans pay the same local tax, our children do not enjoy these lucrative scholarships.—I am, etc.,

"WEST AFRICA."

SIR,—I would like to add my support to the observation made by "Another West Coaster" (June 15, p. 931). For many years I was able to observe newcomers to the service,

ome of whom on arrival were imbued with a warm and yearning desire to 'do good' by the African. But with the passage of time initiative and enthusiasm were dissipated and finally lost in a maze of monotonous routine duties which should devolve on clerks.

In recruitment for the Colonial Medical Service a totally misleading emphasis is laid on the opportunities afforded for clinical and research work. Opportunities there certainly are, material is rich, and the urge to grapple with them not lacking, but the dead hand of officialdom weighs heavily and ever more heavily. Innumerable returns, daily cash collection for the sale of drugs, the checking by auditors and Boards of Survey, elegant clinical work to the background. Interest in the microscope is discarded for a fanatical obsession with "store issue vouchers." Dexterity with a scalpel is replaced by deftness at the typewriter. The outlook of the medical officer becomes completely reorientated until he finally regards efficiency not as the ability to make contact with the people and by raising his clinical standards in his hospital to gain their increasing trust, but as ensuring that his returns are correct, his figures or the annual report impressive, his proposals for the future not too demanding. The impulse to act imperatively in any direction towards betterment must be curbed. Chaos would result. Soon his remaining characteristic is a dexterity for *not* getting things done.

What a waste to the service of imponderable but valuable assets! Surely it is now time to realize that the best will join its ranks only when imagination and driving force are directed towards sustaining a livelier interest in the chief human problem of the country—the sick African—and this not through the medium of clerical routine but by arduous clinical work and profitable research.—I am, etc.,

"STILL ANOTHER WEST COASTER."

Irish Representation on G.M.C.

SIR,—At the present time the power of the General Medical Council is being severely criticized. It has been said that it is very much out of date. I think that its constitution is rather obsolete in regard to the representation of the practitioners of Ireland. As reported in the *Journal* of June 22 (p. 968), one member has been elected to represent the practitioners of Ireland. As the majority of people in England know, Ireland has been divided for almost 25 years into two separate states, the Irish Free State—or Eire, as it is now called—and Northern Ireland. During this time the health services of Northern Ireland have progressed to a much greater extent than those of the Free State. In the latter the only State-aided services are to be found in the "dispensary system"; there is no "panel" service. On the other hand, in Northern Ireland the "panel" service has been instituted for about 15 years (the dispensary system is still present but only serves a very small proportion of the people).

The Minister of Health for Northern Ireland, the Rt. Hon. William Grant, M.P., has stated that it is his policy to introduce a similar health service to that of Great Britain, but not necessarily by the same means. So far as I am aware no such health service is in the policy of Mr. De Valera or his Government. The point I wish to raise is that it is useless for a practitioner from Eire to try and represent the practitioners of Northern Ireland. How can he know anything about conditions of practice in Northern Ireland when he is far from the nearest "panel doctors"? Surely the practitioners of Northern Ireland are to have a direct representative in the General Medical Council. It is most unfortunate that their representative is a man from a State where the way of practice and the way of living are as different as night is from day.—I am, etc.,

Gateshead.

J. S. ELWOOD.

Socialism and the Pay-bed

SIR,—I cannot support too strongly the letter of Mr. J. B. Macalpine (June 22, p. 968). Having worked seven years in a municipal hospital and seen what he describes many times over I feel sure he is right in his protest. If the Hippocratic Oath means anything it binds us to do our utmost to relieve suffering. No political allegiance should be allowed to modify this obligation. In my opinion there is no agony more difficult

to bear than that of the refined, sensitive, and intelligent forced into contact with the foul and the obscene.

What is one to do with a patient who blasphemes and curses, is insolent to the staff and quarrelsome with the other patients? In hospitals under political control this issue is often buried. A patient may make a complaint to a local politician if he is rebuked as he deserves. I have seen nurses and sisters in tears and decent patients boiling with rage because someone is behaving in a detestable manner. Medical superintendents are often afraid to do anything about it. My own remedy on occasion was to put the offender in a side-ward on a milk diet, no smoking, and a rigorous regime, ostensibly for his physical good. Sometimes it worked. But there is no sense and no humanity in compelling people who dislike this sort of thing to make contact with it.—I am, etc.,

Colchester.

G. C. PETHER.

SIR,—Mr. Jas. B. Macalpine's letter (June 22), answering the letter from the medical officers of the Middlesex County Council, expresses admirably what many of us are thinking. What a pity that socialists will try to drag everyone down to a common level. The aim should be privacy in hospital for all those who wish for it, a dragging up to a higher level. Living in a highly socialistic industrial area one has had the opportunity of observing the reactions of leading local socialists to a sick body. Privacy and privileges are wanted, and they are even anxious to pay for them.

Is there not a great deal of humbug in this? Would these medical officers prefer to suffer their next severe illnesses in private or in the company of their social inferiors? Would they put their wives in a general ward or would they get the best they could for them? Unless they are willing to put their socialistic theories into practice on themselves and their families, which is contrary to my experience, they are not justified in their advocacy.—I am, etc.,

Rotherham.

ERIC COLDREY.

SIR,—The whole-time medical officers employed by the Middlesex County Council passed a resolution that "The pay-bed system in hospitals should terminate altogether; patients should receive extra privacy, etc., solely on medical grounds" (*Journal*, June 1, p. 847). This seemed to be so glaringly wrong as to be unworthy of comment, but now that Mr. J. B. Macalpine has written condemning it, I feel compelled to point out that the objections to this resolution are far wider than he states in his letter.

These doctors postulate a new and most frightening ideology. Most of us consider that some control should be placed on extremes of wealth and poverty. Perhaps there are a few who honestly believe that all should have exactly the same regardless of ability or work. But the suggestion of controlling what a man may spend his savings on is new to me. Yet that is what this resolution does. It says in effect: "You shall not be ill in privacy, even if you wish, and we will see that you cannot by not providing the facilities." What right has anyone to say this? If a man wants his wife to have the comfort of privacy during illness, at the cost of giving up smoking for a year, what right has anyone to deny him the chance of spending his money as he wishes?

What would these doctors say if a restriction were placed on the provision of home comforts, so as to bring all homes to a bare level? Is it conceivable that furnishing firms should pass a resolution saying "Hard beds are the best and black curtains the most efficient, therefore we will provide no other." It would be an unsolicited and impertinent effort to manage the public, and so, in my opinion, is the statement of the whole-time medical officers of the Middlesex County Council.—I am, etc.,

London, N.W.1.

R. HALE-WHITE.

Health Service Bill

SIR,—I too am one of the many doctors who view with misgiving the Government's proposals for a National Health Service. I have not seen as yet the pamphlets published by the B.M.A., for distribution by the doctors to their patients. I cannot, however, allow the letter of Dr. A. Angus (June 29, p. 999) to go unchallenged.

In company with many other M.O.s in the Naples area I received orders on the treatment of patients suffering from gonorrhoea which laid down exactly how much sulphonamide was to be given at what intervals and for how long. It also ordered the use of a mixture at specified intervals containing a specified amount of pot.-cit. The terms of this document were specific. They read: . . . "the patient will be given 1 gramme, etc., every four hours for 48 hours" . . . "will be given a mixture containing grs xxx pot.-cit." The whole course of treatment was laid out without hope and room for deviation from beginning to end. I mention this example because the dose of sulphonamide ordered was hopelessly inadequate. Nevertheless, it was some weeks before this highly dangerous order was rescinded.

Dr. Angus must also know that all preventive inoculation treatment in the Army is standardized. An M.O. can only get the material provided by the Army for this purpose and must use it in the way laid down. It may be that for the purposes of the Army it is a highly desirable thing to have doctors whose prime object is to make all ranks fit for duty (though sometimes this was attempted merely by certifying them fit for duty, when the disability was what is now described as psychological). Such doctors are very necessary also in a fascist or communist State. But it is against this very conception of the prime function of a doctor that so many of us are fighting. In common with many other doctors I regard the prime object of a doctor as being "to heal his patient." Furthermore I regard his relationship with his patient in doing so as a highly personal one, and one in which the State and its desires for certification and standard lines of treatment should play little or no part. The patient has in my view good cause to be apprehensive.—I am, etc.,

London, W.9.

A. LEWIS.

SIR,—The statements made by Dr. J. V. DOCKRAY (June 29, p. 999) are inaccurate and, however well-intentioned, may do our cause much harm, and I should like to correct them. On the appointed day all doctors then in practice will have the right to have their names included; those, however, who decline to be at liberty to do so, and therefore the question of a strike does not arise. This could only happen if those doctors who had actually joined the scheme became dissatisfied and refused to work it. I personally have found no indication that the majority of people are in favour of the Bill.—I am, etc.,

Warrington.

THOMAS REES.

Assistants and the Bill

SIR,—The common sense, honesty, and clear thinking evident in Dr. Shackleton Bailey's two letters (June 1, p. 847, and June 29, p. 999) came as refreshing breezes in the somewhat murky atmosphere created in my mind by spokesmen of the B.M.A. and many of your correspondents. We dogsbodies of general practice, the assistants, read with mixed feelings this kind of thing *ad nauseam*:

1. B.M.A. Council's "Principles of the Profession" (March 30, p. 468): "IV. Doctors should, like other-workers, be free to choose the form, place, and type of work they prefer without Governmental or other direction." (My italics.)

2. My old chief, Sir Alfred Webb-Johnson, at Hendon last May 5 (May 11, p. 730): "Ever since Magna Carta it had been the right of the citizen to follow his employment how, when, and where he wished." (My italics.)

3. Dr. Charles Hill at the same meeting: "*We want to avoid the situation that a man or woman, after years of arduous study, and after being recognized as a fit and proper person to practise medicine, finds himself or herself debarred from the area of choice.*" Mr. Bevan has described the procedure as 'negative control,' which does not seem very different to some of us from direction; *by closing certain areas to doctors they will be forced into other areas.*" (My italics.)

We assistants seriously doubt the honesty of purpose of these high-sounding words when we have clauses in our agreements which read like this one (it is operative at the moment in my case although I have chosen to live here mainly because my children are happy and healthy here, and because we love the countryside and its people):

"The assistant agrees with the principals that he will not during this contract of service save in the employ of the principals nor within the space of five years thereafter practise or cause or assist any other person to practise in any department of medicine, surgery,

or midwifery, nor accept nor fill any professional appointment whether wholetime or otherwise, whether paid by fee, salary or otherwise, or whether honorary, within a radius of 10 miles from — aforesaid.

And if the assistant shall so practise or cause or assist any other person to practise within the radius aforesaid or in any way violate this provision he shall forthwith pay to the principals, or as they shall direct, or to their successors in title, the sum of one hundred pounds for every month or part of a month during which he shall violate or continue to violate this provision as ascertained and liquidated damages and not by way of penalty and without prejudice to the right of the principals or their successors in title to obtain an injunction to restrain such violation."

It is the wish of the vast majority of the community here that I should continue to be their family doctor, and a good deal of feeling has resulted from the way I have been treated by the principals. But that is another story. To Dr. R. McIntosh's classification of assistants (June 15, p. 928), however, I would add a fourth group—namely, those of us who, relying on another business contract, the Protection of Practices Scheme found ourselves badly let down and forced to the level of the assistant in order to earn a salary, and so avoid charity to keep our families out of the P.A.I. It has been but one more experience which has convinced me that our profession is by no means as honest and honourable and dignified as the B.M.A. spokesmen would have the world believe. Their hypocritical statements in word, letter, and leaflet are rapidly ensuring the disgust and disdain of many thinking people inside and outside the profession. How much more honest and dignified I would have been to have co-operated wholeheartedly in the Government's task of creating a comprehensive health service which will, without any doubt, not only benefit the patient but the medical profession also. It will, I devoutly hope, raise our status from the business level to which it has sunk during the past 30 years.—I am, etc.,

C. G. JONES.

Ministerial Statements

SIR,—The irresponsible statements of medical policy on the part of responsible Ministers verge on the fantastic. A recent "beauty" to the effect that the best hospitals are located in the wealthiest areas twanged in me a long chord of memory. For as kids my brothers and I were often taken to hospitals, or left outside them, to await the departure homeward of distinguished relatives. And I well remember a small brother, aged 5 or less, in the two-hundred-questions-a-minute phase inquiring: "Mummy, why do they put nasty little houses round all the hospitals?" A long-suffering parent patiently explained that the nasty little houses constituted the original accumulation, the hospital having developed secondarily as an institution designed to benefit the sick and suffering inhabitants of the "nasty little houses"; hence the juxtaposition, and, conversely, the paucity of hospitals in pleasant places.

A much shorter chord vibrates in resonance with another recent statement, expressing a Ministerial preference for survival in the cold efficient atmosphere of a large hospital to dissolution in the warm sympathetic environment of a small one (there being, I take it, no small municipal institutions in the country). I well know a hospital of sufficient proportions to commend itself to the Minister, in which every medical or surgical patient of 70 or over expires most peacefully of broncho-pneumonia within 48 hours of admission. I have conferred with other practitioners whose experience is the same, and we can only attribute the consistency of the result to the preternaturally fine ventilation of the place, the windows being opened wide on the patients all night long in conformity with an official order. "Cold efficiency" is the phrase, the refrigeration proceeding with mathematical precision from first night of warding to mortuary slab. Old folk kept in the warm stuffy atmosphere of their fuggy and ill-ventilated houses (and given the most incompetent and cursory treatment) do not always die, at any rate in the case of normally self-limiting diseases.

Are these Ministerial statements made deliberately falsely, or with reckless indifference to their accuracy or otherwise? It is the differential diagnosis between knavery and folly, and a unique problem in that the greater the degree of the condition the harder it becomes to classify it as the one or the other.

the practical point is that truth and justice go hand in hand, and (whether truth be averted by design or by accident) a government that will not speak truth is not going to do justice. —I am, etc.,

Stratford-on-Avon.

PETER PARRY.

In the Words of Eliza Doolittle

SIR,—After the unfriendly comment of Dr. M. Curwen on Dr. Andrew S. Barr's letter I think it only fair to say some words in support of Dr. Barr. Dr. Curwen must not forget that there are different types of practices in this country. It is an acknowledged fact that practices in industrial and poor urban areas are much harder-worked and poorer-paid than in residential areas with comparatively wealthy populations. If I invited Dr. Curwen to come to County Durham he would be surprised at the low fees and the hard work attached to a club and panel practice, and I believe the same applies to Glasgow. Doctors in this district are really forced to look after far more patients than a single man should do without assistants, even in peacetime, as the overhead expenses—e.g., free medicine and treatment for club members—do not allow the cost of an assistant or partner. In any case, even if the letter of Dr. Barr was slightly exaggerated, I think it was the finest piece of humour I have read for a long time in the *Journal*, and my colleagues in this area share my opinion.—I am, etc.,

Spennymoor.

E. BRAUER.

SIR,—When I wrote my letter some weeks ago, on the day after publication of the Spens report in the *Journal*, I had little expectation of it seeing the light of print, and still less of it raising a furore or a controversy. It seemed to me I could put in less ponderous form, for any plain man or woman to read, the conditions of service under which thousands of general practitioners labour. My letter was neither constructive nor destructive, neither *pro* anything nor *con* anything, just a plain unexaggerated account of what life means to thousands of G.P.s, and a side of the question which is not too well known or appreciated by the general public when our terms of remuneration are discussed—and they are going to be very much discussed in the near future. That I was not unsuccessful in striking a chord in the hearts of many of my colleagues (and their wives) is evident by my mail, which began to arrive within twenty-four hours of the appearance of the letter, and which was to me a striking testimonial to the eagerness with which our *Journal* is read, if to nothing else. My one mistake was in quoting the figure of £1,500—it was too near the desideratum suggested in the Spens report and could be taken as some reflection on it, or some suggestion that it was too low. Nothing could have been further from my intentions. If I had said £10,000 it would have suited my case quite well, and would have avoided any ambiguity, the whole case being that many of us are subject to hours and conditions of labour that no other trade or occupation would tolerate, and it is good that the public should know this when our professional remuneration is discussed.

I am afraid, Sir, that Dr. M. Curwen (June 22, p. 968) is a little off the mark in his observations. Conditions vary in different parts of the country, and it is most undesirable, if not odious, to compare one's remuneration with that of one's colleagues. As he has made some rather unkind inferences, however, I claim the right to inform him that if £1,500 is the target I have never come within sight of it, and I am certain, as the Spens report testifies, that thousands of my colleagues are in like position. His insinuations and innuendoes are therefore invalid, but one would have hoped that a professional colleague would have made sure of his facts before committing his inferences to print. In any case I doubt very much if the principal's paradise envisaged in his letter could ever come to pass, at least in this part of the world, where we try to honour our obligations as laid down in Terms of Service, para. 11 (8).

The answer to his last question as to what would happen if I refused to answer requests at my meal hours is simple. The door-bell would continue to ring (requests have to be made before they can be refused) and the summons would be answered, I hope, with native courtesy by wife or maid, while the local butcher, baker, and candlestick-maker enjoy their meals with their families in the peace and quietness to which they are absolutely entitled.—I am, etc.,

Glasgow.

ANDREW S. BARR.

Obituary

GEORGE JESSEL, M.A., M.D., D.P.H.

The sudden and entirely unexpected death of George Jessel has thinned once more the ranks of the old guard of tuberculosis officers who took office in 1913. Ambitious, able, clear-headed, he was a stout fighter for all the best methods in the prevention and treatment of tuberculosis; and he had good scope in Lancashire and on many councils and committees to use his abilities, which were much above average level. Exacting and sometimes difficult to his subordinates, he never spared himself either in his own work or where assistants required defence. He combined first-rate clinical work with that degree of administrative ability which together makes the outstanding tuberculosis officer.

He graduated in 1906 from University College, Oxford, took his M.A. in 1909, and qualified from the London Hospital the same year. Resident for a year at the London, where he had won the Anderson Prize in clinical medicine, and also for a year at the Great Ormond Street Children's Hospital, he then spent two years in private practice. The D.P.H. at Manchester in 1913 under Delepine, when he was first man of the year, and the M.D.Oxon in 1917 completed a varied and successful medical training.

It was in 1913 that Jessel started work in tuberculosis, when he was appointed tuberculosis officer for a Lancashire County area and also for the County Borough of Wigan. This, like other similar appointments, was an interesting experiment which failed because the tuberculosis officer was under two masters. He also was acting M.O.H. of Wigan from 1914 to 1917. In 1919 he became consultant tuberculosis officer of the Lancashire County Council. Thus for 33 years he was in charge of Dispensary Area 4 containing a population of some 370,000, and including the Peel Hall Pulmonary Hospital, of which he was the visiting medical superintendent. There he did excellent work, especially with artificial pneumothorax. He introduced a system of graduated work and hobby occupations for the patients to vary the monotony and benefit the patients physically and mentally. In his own words: "The tuberculosis officer who aims at realizing the ideals of his office must undertake somewhat the role of schoolmaster and cleric as well as medical specialist." And no mean part of his reward lay in the volume of appreciation of the patients. The integration of hospital with clinic and domiciliary work carried out by a team, which has been the foundation of the Lancashire scheme, had its birth in Dr. Jessel's area, and his successful advocacy and carrying out of this sometimes difficult union played a prominent part in its adoption for the whole administrative county.

For many years Dr. Jessel was connected with the N.W. Branch of the Society of Medical Officers of Health and the N.W. Tuberculosis Society, and was a past president of both these bodies. He took a great interest in the Joint Tuberculosis Council, for long was its treasurer, and at the time of his death vice-chairman. His wide knowledge of tuberculosis and clear vision of its public health and social implications were always at the service and to the benefit of the many committees of the council on which he served. His main hobby was photography, hence his enthusiasm for x-ray work, which he carried out at a high level and which made him a valued member of the Minister of Health's committee which prepared the way for mass miniature radiography.

To his widow, son, and two daughters we extend our sympathy in their bereavement.

G. L. C.

JAMES TAYLOR, M.D., F.R.C.P.

Dr. F. M. R. WALSHE, F.R.S., writes:

An old house physician of Dr. James Taylor, a warm admirer of him as man and as physician, and the recipient from him of many kindnesses and much encouragement, I may not forbear to add my modest tribute to the one paid by Dr. Gordon Holmes to his memory. It is an act of historical justice to recall that Taylor's was the first adequate account given in this country of the malady

we now know as subacute combined degeneration of the spinal cord. In his paper (*Medico-Chirurg. Trans.* 1895, 78), based upon the complete clinical and pathological study of two cases, Taylor recognized the two clinical variants of the malady, the spastic and the flaccid, and correlated them with the relative incidence of the lesion in the posterior and lateral columns of the cord. Of this lesion he gave an excellent account and some admirable photomicrographs. There can be no doubt that our modern clinico-pathological notion of the malady dates from the appearance of this paper. Perhaps, however, those of my generation may feel that his major contribution to British neurology was the handing on of the tradition and the legend bequeathed by the great figures of the golden age of neurology in this country. If we who have inherited these succeed in passing them intact to those who must follow us, we shall not have toiled or taught altogether in vain.

By the death of EDGAR HENRY WILKINS the school medical service has lost one of its most active minds. His father was headmaster of the Dublin High School, his uncle, Prof. George Wilkins, was a leading personality in Trinity College, and his mother was one of the early entrants at Newnham College, Cambridge, so his student days were spent among notable men. He graduated M.B., Ch.B. at Dublin University in 1912, and took the London Conjoint D.P.H. in 1924. Apart from his enthusiasm for school medicine, Wilkins was a keen athlete and a successful racing cyclist. He also climbed the mountains in Wicklow and in Wales, and was an authority on the bird life in the countryside around Dublin. Many leisure hours he spent in the intensive study of chamber music; but as a keen gardener and carpenter he found his greatest pleasure in his home life or in the company of his devoted wife and family. After qualifying, Dr. Wilkins spent ten years in New Zealand, where he worked with Sir Truby King and became director of the Dominion school medical services. On his return to England he was appointed to the school medical staff at Birmingham, and in that capacity he served for the rest of his life. He was interested in all phases of public health, but his chief enthusiasm was school medicine. He put his heart into this work and viewed it from a wide angle. He had all the keenness of a pioneer without the fanaticism. To his school work he brought not only sound clinical knowledge but also deep personal interest in the patient. His influence was widely appreciated, and his loss is deeply felt by the parents of the children in a crowded industrial area to whom he devoted his energies and talents, as also by the teachers of schools under his care. At the recent link-up between the Birmingham School Health Service and the Institute of Child Health, the choice naturally fell upon Wilkins to represent the school health activities in relation to the institute.

We regret to announce the death of Dr. HOWARD HENRY at Debenham, Suffolk, on June 24, aged 70. Son of James Henry, of Dublin, he had his medical education in that city at Trinity College, graduating B.A. in 1897, M.B., B.Ch., B.A.O. in 1900, and M.D. in 1906. Before leaving Dublin he served as medical and surgical resident at Adelaide Hospital and Stevens' Hospital, and took the L.M. at the Rotunda Hospital. It was about that time that he contributed a note to these columns on calculation of the date of delivery in pregnancy. Dr. Henry served with distinction in the war of 1914-18 as a major in the R.A.M.C.(T.), winning the Military Cross and the Territorial Decoration. On returning to civil life he was for a time medical superintendent of Leopardstown Park Hospital (for neurasthenic cases) under the Ministry of Pensions. He joined the B.M.A. in 1904, was elected chairman of the South Suffolk Division in 1928, and represented it at two Annual Meetings. He was for some years medical officer and public vaccinator for the Debenham district.

Many people will have learned with sorrow of the death on June 26 of Lieut.-Col. ALFRED WHITMORE, M.D. Cantab., who had a distinguished career in the I.M.S. Apart from his service with the Army in the 1914-18 war, most of his service was in the Civil Department in Burma. He was for some years pathologist to the Rangoon General Hospital, and afterwards one of the Rangoon civil surgeons. He had a great deal to do with the early development of the Burma Medical School, and he was an original and stimulating teacher, for whom students, nurses, patients, and all his colleagues had a warm affection. After his retirement from the I.M.S. he worked in the pathological department at Cambridge, and although he underwent an extremely serious operation three years ago and had grave disabilities, he stuck to his work with great fortitude until a few days before his death. Whitmore was a most lovable man with a very keen sense of humour, and all who knew him well

were greatly attached to him. He seemed to radiate something buoyant and joyous, and the outlook always seemed brighter when he was about. Those who had the privilege of his friendship will miss him sorely. He leaves a widow and two sons, both of whom are medical men. R.K.

The following further tribute to Squadron Leader R. W. S. MARSHALL comes from Dr. J. Kinloch McCollum: "I knew Robert Marshall in his late school years and as an undergraduate at medical school. I met him again during the war years, first in Assam and later throughout Burma from time to time. I had looked forward to meeting Robert again on the Burma-China border, where he was expected to take up an important duty, and news of his loss came as a profound shock to me. We all refused to believe that he had been killed, and kept on hoping that he would eventually be recovered by comrades on patrol or by friendly natives; this was not to be. Robert had the grand gift of making genuine friends, of being able to give more than he ever expected to receive, of sincerity and lovable charm. He had a modest disposition, and his frank and open personality created for him true and lasting friendships. I met Robert for the last time less than two months before he embarked on the detail of duty which was to mean his death. He talked to me of his home, of how he was looking forward to his approaching repatriation, of his experiences and how he meant to benefit by them in his future relations with mankind. His outlook was filled with high ideals of service, and his motto was 'deeds not words.' He had a deep affection for those with whom he served, especially his men and N.C.O.s. This was a reciprocal affection, and based on mutual regard of men for each other who daily faced the reality of living and the uncertainty of life. Robert was always happy when giving not only professional advice to his sick, but also when he was able to help and succour those in need, and these were many in the dark days of 1943 and 1944 in Burma. He carried a flame of hope to all in pain, and was a source of comfort to those in trouble. Robert, I know, willingly gave his life, not only for King and Country, but also for principles which he believed in and which he had the conviction to effect; greater courage hath no man than this."

The Services

Major-Gen. O. W. McSheehy, C.B., D.S.O., O.B.E., has been appointed Col. Cmmtd. of the R.A.M.C., in succession to Major-Gen. H. P. W. Barrow, C.B., C.M.G., D.S.O., O.B.E., who has attained the age limit.

Col. (Temp. Brig.) A. E. Richmond, C.B.E., late R.A.M.C., has been appointed Honorary Surgeon to the King in succession to Major-Gen. G. Wilson, C.B., C.B.E., M.C., late R.A.M.C.

Col. R. W. Galloway, C.B., C.B.E., D.S.O., late R.A.M.C., to be D.D.M.S., and has been granted the acting rank of Major-Gen.

Col. F. M. Collins, I.M.S., has been appointed Consulting Surgeon, India Command.

Temp. Surg. Lieut.-Cmdr. R. G. S. Whitfield, R.N.V.R., has been awarded the D.S.C., and Surg. Lieut. A. W. Dawson-Grove, R.N.V.R., has been mentioned in dispatches, for distinguished services during the defence of Hong Kong and while prisoners of war in enemy hands.

DEATHS IN THE SERVICES

Flight Lieut. IAN ARCHIBALD McLEAN THOMSON, who was killed in a flying accident on June 25, was born in October, 1916, studied medicine at Glasgow and qualified L.R.C.P.&S., L.R.F.P.S. in 1942. After holding house appointments at the Glasgow Royal Infirmary, he was granted a commission as flying officer in the Medical Branch, Royal Air Force Volunteer Reserve, in January, 1944, becoming Flight Lieut. a year later.

On June 20, Surgeon General Thomas Parran, chairman of the U.S. Delegation to the International Health Conference, was nominated chairman of the Conference. After serving in 14 States on public health research and administrative duties, and from 1930 to 1936 as Commissioner of Health for the State of New York, Dr. Parran was appointed Surgeon General of the U.S. Public Health Service. He was reappointed in 1940 and 1944 and on numerous occasions was representative to international conferences. In February, 1941, he came as a member of the U.S. Commission to England to study health conditions, epidemic control, transportation, and evacuation of children in Great Britain.

Medical Notes in Parliament

HEALTH SERVICE BILL

On July 2 the Committee resumed discussion of Clause 69. Mr. BEVAN explained that the question at issue was the matters contained in the Bill which should, respectively, be subject to affirmative resolution by the House, to negative resolution, or to Orders.

DISTRIBUTION OF HOSPITALS FUND

Mr. WILLINK raised the status of the Minister's actions under Clause 7, subsection (5c), under which the Minister could make regulations for apportioning among the regions the capital value of the hospitals fund. The Minister was going to put into one pot the gifts which countless people had made to hospitals throughout the generation. In some areas substantial sums would be added, and from other areas substantial sums would be subtracted. The Minister was being entrusted with a function which the Bill should bind him to explain to the House. As the Bill stood, what the Minister did in that respect would only be subject to a negative resolution.

Mr. BEVAN said the qualitative issue, whether this fund should be used in this way or not, had already been determined. The House of Commons did not want to bother with the quantitative distribution of the fund because that aroused the utmost prejudice in different parts of the country.

Mr. WILLINK pointed out that, since the issue of the White Paper, Parliament had not been told whether the Minister was moving in the direction of a large number of regions—say 16 to 20. It had been told that the regions were not to be geographical areas, but had not been told whether the L.C.C. would be the local authority for an area which was also the area of a regional hospital board, or whether there was to be something like the sectors of the Emergency Hospital Service. Those interested in Wales did not know whether Wales would be a region. All that the Conservative Opposition desired was apportionment among the regions, not among the hospitals.

Mr. BEVAN said it should be remembered that the Ministry would deal with the competing claims of different hospitals, and that one hospital would be given money out of the fund at the expense of another. The "global" figure would remain the same. No Minister worth his salt was going to distribute that fund except with the intention of having the healthiest kind of service in the areas, and in the most equitable fashion. This was the sort of thing which the House of Commons could properly leave to administration, just as it had set aside the sum of £66,000,000 for compensation for the loss of the sale of goodwill. The apportionment of that money to the doctors concerned was also a matter of complexity, and possibly acrimony, and the House of Commons would prefer it to be left to the civil servants.

The amendment proposed by Mr. Willink was defeated by 22 to 10. The Committee then accepted an amendment moved by Mr. BEVAN to make subject to a negative resolution of Parliament any order of the Minister varying the constitution of the central health services council. The Clause as amended was ordered to stand part of the Bill. Clauses 70 and 71 were accepted in their original form.

On Clause 72 Mr. BEVAN moved an amendment which he said was necessary because in certain circumstances under the Asylums Officers Superannuation Act, 1909, a visiting committee paying a superannuation allowance to a retired employee was entitled to call upon other visiting committees who had previously employed him to make a contribution towards the allowance. The purpose of the amendment was to see that no injustice was done to individuals in these cases. The Clause with this amendment was ordered to stand part of the Bill.

Mr. KEY moved an amendment on the passage dealing with the definition of hospitals in Clause 73. He proposed to leave out the words "providing treatment" and to insert "the reception and treatment of persons." He said it was desired to make plain that the hospital was a residential building for the reception of people for convalescent and rehabilitation treatment. This amendment was accepted, as was a further amendment moved by Mr. Key specifying dental as well as medical treatment in the definition of illness requiring treatment. The Committee also accepted Mr. Key's definition of "superannuation benefits" as meaning "annual superannuation allowances, gratuities, and periodical payments payable on retirement, death, or incapacity, and similar benefits."

DEFINITION OF A SPECIALIST

During discussion on the motion that Clause 74 stand part of the Bill Mr. WILLINK pointed out that the Clause did not

provide any definition of "consultant" or "specialist." Mr. MESSER said the National Institute for the Blind were anxious to know whether blindness was an illness. He further inquired whether deafness was to be an illness. He thought it would be better if the Bill said that "illness" included mental illness and any injury or disability, without requiring medical treatment or nursing. In London at the Tavistock Clinic there were medical men, but a stage arrived when the cases were referred to a lay psychiatrist when what was wanted was not so much medical treatment as social welfare treatment.

Mr. BEVAN said the less Members attempted to penetrate into this topic the less difficulty they would get into. He agreed with much that Mr. Messer had said. He would take the advice of the medical profession on the definition of "specialist." At the moment he did not know what it was, and the profession had not a definition which was precise enough to put into the Bill. Furthermore, there would be general medical practitioners who, although they were classified as such, had shown that they could be relied upon to give a particular form of treatment as well as a specialist who had academic qualifications in the subject. The Ministry wanted to leave the question to the advisory bodies operating through the Minister and the regional boards to define those particular general practitioners *ad hoc* as specialists for the purposes of the administration. That was the more necessary because there was an inadequate supply of specialists with objective specialist qualifications. Mr. Bevan promised that in this matter he would move with the greatest possible caution.

The Clause as amended was ordered to stand part of the Bill, and Clause 74, the last Clause of the Bill, was approved without discussion.

PROVISION OF SPECIAL SCHOOLS

Mr. KEY then moved a new Clause. This provided that a regional hospital board or board of governors of a teaching hospital might, with the approval of the Minister, arrange with any local education authority or voluntary organization for the use of any premises forming part of a hospital administered by the regional hospital board or, as the case might be, forming part of the teaching hospital, as a special school, and for the maintenance of children other than patients attending such a school. Mr. Key said that normally children receiving this instruction would be patients in the institution, but there were cases where subnormal children were brought from their homes to classes in some of these institutions.

The Clause was added to the Bill, as were other new Clauses dealing with exemptions from stamp duties on certain documents required for the purposes of the Act, and with the supply of goods by local health authorities.

INDUSTRIAL MEDICINE

A new Clause moved by Mr. PIRATIN enjoined the Minister to prepare within five years a scheme for the study and control of conditions of work; prevention of occupational disease and injury, placement, and periodic medical examination of workers, health education of workers, record-keeping and research. Dr. MORGAN remarked during the discussion that up to the present research into industrial medicine in the United Kingdom was slight. There was not even a decent industrial diseases museum. Mr. BEVAN said a preventive health service would cover the whole of the ground with which Mr. Piratin dealt. Nutrition and housing would go most of the way towards providing that service but had nothing to do with this Bill. In the course of time the health service under this Bill would assimilate by its administrative momentum a considerable amount of industrial health services. Many of the provisional facilities which were now given in some workshops would be provided by the general health service. He hoped that before the end of this Parliament the Government could envisage the future industrial health service more clearly than at present, though he could not promise legislation. The proposed new Clause was withdrawn.

Mr. SOMERVILLE HASTINGS moved a new Clause on the application of the Bill to London, but it was negatived.

NOXIOUS NOSTRUMS

Mr. Linstead moved but withdrew a new Clause to provide that the Minister should appoint a committee, including persons expert in medicine and pharmacy and persons having practical experience of the proprietary medicine industry, to prepare for submission to the Minister a list of medicines the prescribing of which by medical practitioners for the purposes of the Act was not recommended, or with respect to which the public were cautioned as to their use because they were without physiological effect, or the price at which they were sold was excessive, or they were advertised by claims that were false or exaggerated.

Mr. BEVAN said he sympathized with the intention behind this Clause. These noxious nostrums were so seductively advertised that hard-headed people were taken in. The subject, however, was too wide to bring in at the end of a Committee stage and doctors themselves would say that the Clause as drafted was an interference with their right to prescribe. Herbalists and other people would insist on being heard before legislation of this kind was introduced. The time had arrived when the public of this country should be protected against the ramp that was going on, but the subject must be dealt with in entirely separate legislation. He regarded the matter as of some urgency.

Col. STODDART-SCOTT said the new Clause did not suggest that Parliament should deprive the community of such useful drugs as Eno's, Californian syrup of figs, or senna pods, but only the bogus things, such as one saw advertised every day.

Mr. WILLINK moved but withdrew a new Clause proposing that the Minister could make grants to national bodies engaged in securing improvement in the physical or mental health of the people, and instanced the Provisional Council of Mental Health and the Tuberculosis Council. Mr. BEVAN said these words were unnecessary as he already had wider powers under the Health Act, 1919, and under Clause 1 of the Bill.

THE CENTRAL COUNCIL

Several amendments were down to the First Schedule, and the Chairman, Mr. Bowles, allowed a general discussion. Capt. BAIRD said that under the Bill there were six *ex officio* members of the Central Council, including the Presidents of the three Royal Colleges, the Chairman of the British Medical Association, and so on. The dental practitioners claimed to be represented by the Chairman of the Dental Board. The medical profession had 20 representatives and the dentists only three.

Mr. WILLINK said he had tabled amendments. The Committee did not want a medical hegemony in the National Health Service. The most admirable physicians and surgeons were often most unpractical in thinking out administrative methods. The five persons with experience of hospital management and the five persons with experience of local government who were to be placed on the central council should not be doctors but should be the lay elements on the council. Mr. BEVAN said he agreed with this. He hoped there would be no auctioning of seats on this council. He thought the doctors were in a position because they had an over-all responsibility for the health services and covered services like radiology and surgery. The Committee would work more through sub-committees than as a whole. The Ministry wished to bring into the central council the fresh air of lay approach. It was necessary to have strong lay representation to get an effective service.

Mr. HASTINGS said he inclined to look on the council as an overdoctored area. The Committee accepted amendments to provide that the ten members of the council mentioned by Mr. Willink should not be medical practitioners. Other amendments were withdrawn.

Mr. BEVAN then moved an amendment to provide for the payment of expenses to members of committees or sub-committees set up by the central council. This was carried by 23 to 11, and the Schedule as amended was agreed to.

On the motion that the Second Schedule stand part of the Bill, Sir H. LUCAS-TOOTH said under the Schedule compensation was payable for hospital buildings and land, and also for equipment, furniture, and so on. The total compensation paid in respect of a hospital would be merely for the break-up value of the undertaking. Mr. BEVAN pointed out that arbitration was provided. The Committee agreed to the Schedule.

REGIONAL HOSPITAL BOARDS

On the Third Schedule Mr. WILLINK said that as the Schedule stood there was no guarantee against representation of a particular branch of those interested. It would be possible to get the regional hospital boards too medical or too lay. He suggested that the representation should be made up of university, professional, local health authority, and other persons, and, in the first instance, of those representative of the old voluntary hospitals. Provision should be made for the appointment of persons having experience both of public service and of financial and commercial affairs. Due regard should be had to the representation on a board of members of boards of governors of teaching hospitals.

Mr. BEVAN said it would be better to keep this matter within the administrative powers of the Ministry. Regional boards would vary considerably in size. It had been suggested there should be one regional board for Wales, but Wales had only one university medical school, in Cardiff, and there might be administrative convenience in having one regional hospital board for Wales with both Cardiff and Liverpool universities

represented on it. Hospital administration and economy were not necessarily jobs which doctors could do best. Individually they were most charming and educated persons, but because of their immersion in their profession their collective sagacity was not the sum of their individual intelligence. He asked the Committee to retain the language already in the Bill. He added that the Ministry must call upon the rich experience in the field of voluntary hospital administration.

Mr. WILLINK withdrew his amendment, and Mr. KEY secured approval for amendments to provide for consultation between the management committee appointed for a particular voluntary hospital and the committee which had previously been responsible for running the hospital. By 19 to 8 the Committee rejected an amendment proposed by Mr. WILLINK empowering a hospital management committee to co-opt not more than three persons.

CONSTITUTION OF BOARDS OF GOVERNORS

On July 3, resuming the discussion of the Third Schedule, Col. STODDART-SCOTT moved an amendment dealing with the constitution of boards of governors of teaching hospitals. It suggested that the boards should consist of such number of members to be appointed by the Minister as he thought fit, but that one-sixth should be nominated from the universities, one-sixth by the regional hospital boards, one-sixth by the medical, dental and other members of the teaching staff of the hospital, one-sixth after consultations with the local health authorities, and that other persons should be appointed from the governing bodies of the hospitals. Boards of governors should have power to co-opt not more than three persons, and should have the opportunity of electing their own chairman with the concurrence and agreement of the Minister.

Mr. BEVAN said if the balance of the Bill was altered grievances would be established. Mr. WILLINK said the proposed constitution would be better for a body of a quasi-university character. In such institutions as Guy's Hospital and St. Thomas's there was a special claim for continuity with their past. He hoped the Minister would agree that after something like two-thirds of a hospital board had been appointed by him after nomination, the remaining one-third should be chosen from the existing board of governors so as to give continuity. Why did the Minister wish to choose the chairman for a body of this kind? The normal thing was that all bodies chose their own chairman though the Committee had conceded that the Minister should nominate the chairman of regional boards and management committees.

Mr. SOMERVILLE HASTINGS thought the one-fifth representation proposed in the Bill for universities was too little. He would oppose its reduction from one-fifth to one-sixth.

Mr. BEVAN said university people would argue that universities ought to be more represented, but the Government did not wish to over-emphasize the academic aspect. Teaching hospitals were part of the general hospital service and were expected to give general hospital facilities. That was why it was necessary that the teaching hospital in its administration of the general hospital service should be as much an agent of the Minister as the regional board. In the appointments of these new boards of governors the Ministry would have regard to the existing boards. The more the distinct position of the boards of governors was increased the more the Committee would appear to reduce the status of the regional boards. The Ministry must resist the importunities of the teaching hospitals. At the moment the universities had scarcely any representation, and this Bill for the first time regularized the relationship between academic medicine and hospital administration. That was what the Goodenough Committee recommended. Mr. BEVAN added that he thought it reasonable in this as in all other cases that the chairman should be a person agreeable to the rest of the board of governors but a person appointed by the Minister.

The amendment moved by Col. Stoddart-Scott was negatived and drafting amendments were made on the motion of Mr. KEY.

Mr. WILLINK moved to provide that where a teaching hospital comprised more than one hospital a committee should be appointed by the board of governors of the teaching hospital for each such hospital. Mr. BEVAN said this should be left to be decided in the circumstances concerned. Mr. Willink withdrew his amendment. Mr. REID moved but withdrew an amendment to provide that representatives of the Press should be admitted to the meetings of every regional board. The Third Schedule as amended was then agreed to.

LOCAL HEALTH AUTHORITIES

On the Fourth Schedule Mr. KEY moved a series of amendments which were accepted. He explained that one of them was designed to enable the local authority to give to its health committee functions which it had under other Acts in addition to those which it had in connexion with child welfare, midwifery, lunacy, and mental deficiency.

Prevent Discomfort

IN HAY FEVER AND SUMMER COLDS

To the hay-fever victim the use of 'Benzedrine' Inhaler may make all the difference between weeks of acute misery and weeks of comparative comfort. Its vapour diffuses throughout the entire nasal cavity and is strikingly effective in reducing the intense congestion which makes allergic rhinitis so distressing.

Head colds are particularly annoying during the summer. 'Benzedrine' Inhaler helps to cut them short and provides welcome symptomatic relief.

Each tube is packed with Amphetamine (B.P.) 325 mgm., Oil of Lavender 97 mgm., Menthol 32 mgm.

THE VAGINAL TAMPON

—a significant contribution
to physiological and psychological
well-being

PRODUCED after the most careful study of the anatomy of the vagina and the cervix in relation to normal menstruation, Tampax tampons were designed to alleviate the mental strains and physical stresses associated with the menstrual period.

The principle of the surgical tampon embodied in Tampax has found solid support among women doctors, matrons and nurses. Sense of security and comfort, the ability to live normally and move freely during the period—these are the main benefits behind this growing acceptance of Tampax, in which physical and psychological aspects are closely related.

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

Mr. WILLINK moved an amendment to ensure that every health committee of a local health authority should include one or more medical practitioners providing general medical services in the area or specialists serving on the staff of a hospital within the area.

Mr. BEVAN said he had considered this point when the Bill was being framed, and had rejected what was now proposed on the ground that the scheme which he had devised provided a great degree of professional self-government and professional participation in the health services as a whole. Very often these professional people were elected as councillors, and it would be resented if an elected body were compelled to elect some persons who had not taken the trouble to stand for election. If a medical practitioner were not too busy to serve on this important body for three years he could take the trouble to stand for election. The amendment was negatived and the Fourth Schedule as amended was agreed to.

EXECUTIVE COUNCILS AND LOCAL MEDICAL COMMITTEES

On the Fifth Schedule Dr. CLITHEROW asked the Minister to consider allowing a representative from the optical practitioners committee on the executive council. He remarked that the provision of two members appointed by the pharmaceutical committee appeared to be rather small as there were 14,000 contracts with the Ministry of Health to carry out pharmaceutical services.

Mr. BEVAN said the ophthalmic services would be a feature of the regional boards and not of the executive councils. The executive council was the body supervising the general medical practitioner service in the area. It had been constituted with scrupulous care, and any attempt to upset the balance would have repercussions almost as great as the atomic bomb.

The amendment was negatived and the Committee agreed on the motion of Mr. KEY to insert "Local Medical Committee" instead of "Medical Practitioner Committee" in the provision that seven members of each executive council should be appointed by this body whose title had previously been changed.

MEDICAL PRACTICES COMMITTEE

In the Sixth Schedule the Committee negatived a proposal by Mr. WILLINK to provide that the chairman and members of each such committee should be appointed by the Minister "from among medical practitioners nominated for the purpose by such organization or committee." The Schedule was then agreed to. Amendments were made on the motion of Mr. KEY in the Seventh Schedule. The deputy chairman of the tribunal would be appointed by the Lord Chancellor and not by the Minister, and one member would be a layman. The Committee agreed to the Schedule with these amendments, and also to the Eighth Schedule.

More than 50 amendments were made in the Ninth Schedule. Mr. BEVAN said the extension of the existing lunacy machinery was a very complicated affair. The Committee was not altering the lunacy code but was extracting mental institutions and care from a whole series of enactments and services. It had been discovered during the Committee stage that some enactments or parts of enactments had been overlooked. This series of amendments was necessary to put the matter right.

All the amendments proposed by Mr. Bevan were accepted, the Schedule as amended was agreed to, and numerous administrative amendments were made in the Tenth Schedule, which, with these changes, was also accepted.

This was the last Schedule and the Committee agreed that the Bill as amended should be reported to the House.

Control of Penicillin

On June 27 Mr. E. P. SMITH moved that the Control of Penicillin (No. 1) Order, 1946, dated May 21, be annulled. He said the Order was too limiting and restrictive in one respect and slightly too wide in another. He recalled that Sir John Mellor had asked on June 20 why this Order required prescription of penicillin by a registered medical practitioner whereas prescription by a duly qualified medical practitioner satisfied the Pharmacy and Poisons Act, 1933. The Government reply had been that by the Medical Act, 1858, the two expressions were synonymous, and that current drafting practice favoured the former. Mr. Smith objected that the Order which he challenged made no mention of the unregistered medical practitioner and his patient. Doctors who had been struck off the Register by the G.M.C. for reasons unconnected with their medical skill would be debarred from the use of this invaluable drug. The offences for which a doctor might be struck off varied, but the one charge which the G.M.C. could not bring against the doctor was that his theory of medicine was wrong. That was specifically mentioned in the Act of 1858. Doctors who had been struck off the Register were free to practise but they could not sign a death certificate

and could not prescribe dangerous drugs. He went on to refer to the case of Dr. Hennessy.

The Speaker ruled that on the Order under discussion the House could not debate the actions of the G.M.C.

Mr. C. S. TAYLOR suggested that because penicillin was not a dangerous drug it should be permitted to people who were not qualified medical practitioners. The Speaker replied that this might be so, but it would not be in order to go into the details of unregistered people who might supply this drug. Mr. TAYLOR seconded the motion for rejection of the Order. He said there was no excuse whatever for limiting penicillin when anybody could go into a chemist's shop, buy a bottle of aspirins, and kill himself. There was a consensus of opinion in the medical profession that penicillin would not do any harm. It would not necessarily cure, but it would not kill.

Mr. DAVID ECCLES said penicillin was a drug which was useful for animals, and experiments were going on which would be very useful indeed in the livestock industry. He asked how it was possible for a veterinary surgeon to get the drug under this Order.

Replying for the Government, Mr. LEONARD said the production of penicillin had been widely developed, and in the United Kingdom £3,000,000 had been spent in plant and factories; of that total £2,000,000 was Government money. Penicillin was one of the most potent cures for certain diseases but was not a universal cure. Its indiscriminate use might be attended by grave consequences. There was a danger of spreading strains of bacteria which were resistant to penicillin if it was improperly used. There were two methods in the production of penicillin. The earlier was that of surface culture. That method would be substantially departed from by the end of June, leaving the new deep culture responsible for by far the greater bulk of the production, which would come mainly from a factory at Speke and another at Barnard Castle. The average monthly production of penicillin in 1943 was 300 mega units. In 1944 it was 3,200 mega units. In 1945 it had grown to 6,000 mega units a month. Penicillin made available by June production this year would be about 300,000 mega units. From this total some 56,000 mega units would be allocated to the Services. Export licences had been granted for 130,000 mega units, leaving about 120,000 for home consumption. Production was expected to increase substantially over the next few months. Britain was not now importing penicillin. Greater production had made distribution possible through commercial channels from June 1, and such statutory control as remained had been arranged largely at the request of the trade. The supply situation would not allow of uncontrolled distribution which might result in the experience of America, where penicillin was diverted to trivial uses. It was impossible to forecast the civilian demand for penicillin. Until commercial distribution had been in force for some months the Ministry of Supply must ensure that it was available in full quantity for the genuine medical user rather than for general needs. On the advice of the bodies concerned it had been decided to make it freely available to hospitals, doctors, and dentists, and for it to be sold to the general public by chemists only on production of a certificate from a qualified practitioner. It was also decided to restrict the manufacture of items with penicillin content to such things as the Minister of Supply, with the approval of the Minister of Health, should advise.

With regard to the veterinary use the position was still as stated on May 20 by Mr. Tom Williams. There were sufficient supplies for approved veterinary research, but until the demand for human needs was known it would be impossible to indicate what supplies would be available for the treatment of dairy cows generally. Penicillin was of particular efficacy in the treatment of mastitis, and adequate supplies had been made available to the Ministry of Agriculture for experiment, and large-scale field trials were being carried out. Penicillin was not a poison or a dangerous drug, but might produce harmful results if used without medical guidance. The main reason for limitation was to prevent it being frittered away on trifling uses. The reference in the Order to Government departments was put in to enable penicillin to be used for veterinary purposes. The question of medical practitioners was one for the Minister of Health.

Sir IAN FRASER said he was not convinced that drugs which were controlled should be made available to unregistered medical practitioners, but he objected to the control of drugs unless they were poisons.

Col. STODDART-SCOTT asked whether Mr. Leonard in his remarks referred to liquid and crystal penicillin or to preparations made from penicillin, like toothpaste, creams, and ointments. The public ought not to have to go to a doctor to get a prescription for penicillin toothpaste as soon as it became available. It should be used by everybody, and the creams and ointments should be in every household as a protection against simple ailments. He hoped the Government departments

would be able to issue penicillin for human research as for agricultural research, because some of the qualified medical men who carried on research in the great medical schools preferred to have none of the inhibitions of the G.M.C. associated with them, and therefore they had not their names on the *Medical Register*.

Mr. Smith's motion to annul the Order was defeated by 145 to 45.

Propaganda against Immunization.—Sir E. GRAHAM-LITTLE inquired on June 18 whether Mr. Bevan had considered the printed circular which the National Anti-Vaccination League sends to parents of newly born children, declaring that immunization against diphtheria is dangerous and ineffective; and what action he proposed to take to prevent this interference with his Department's immunization campaign. Mr. BEVAN said he was aware of these circulars. He was confident that parents would look at the facts rather than at propaganda of this sort. He made it his business to make the true facts well known.

Universities and Colleges

UNIVERSITY OF OXFORD

At a Congregation on June 15 the degree of D.M. was conferred on R. D. Newton, and that of B.M. on T. J. Thompson.

On July 1 the degree of D.Sc., *honoris causa*, was conferred on Prof. James Bertram Collip, F.R.S., director of the Research Institute of Endocrinology at McGill University, Montreal, and chairman of the Associate Committee of Medical Research of the National Research Council of Canada.

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

FINAL M.B.—Part II (Principles and Practice of Physic, Pathology, and Pharmacology): D. M. C. Ainscow, G. S. Andrew, A. V. G. Bibby, M. O. Birkbeck, E. A. D. Boyd, D. K. Briggs, B. H. Brock, J. A. Bulleid, E. H. W. Burt, H. C. Churchill-Davidson, I. F. J. Churchill-Davidson, L. W. Clarke, J. W. Coleman, G. Cox, D. J. Crockett, P. S. Davis, J. R. B. Dixey, W. M. Edgar, H. S. Eyre, J. G. Franks, J. B. Frost, T. C. Gibson, L. Haas, A. W. I. Hall, J. G. Harrison, P. L. M. Hartley, W. J. Hay, P. M. R. Hemphill, Hetherington, P. F. C. Jackson, J. H. Jacobs, K. E. Jefferson, A. G. Jessiman, W. Ker, G. L. Leathart, J. D. Lever, R. H. G. Lyne-Pirkis, E. L. McDonald, Melver, R. W. J. MacLure, W. D. Mail, K. E. Marsh, H. G. Mather, T. R. E. P. G. Michell, D. T. Milnes, D. R. Morgan, I. M. Ormerod, J. V. Owen, I. M. Ramsden, R. Randall, P. Rhodes, J. S. Rivers, O. C. A. Scott, J. G. Selwyn, M. Shirley, D. R. Smith, J. S. Swallow, C. E. D. Taylor, R. J. D. Temple, K. Till, M. K. Towers, H. W. Trusted, S. Vakil, W. van't Hoff, D. R. Wallace-Jones, D. B. Wallis, W. Wardill, I. W. Whitmore, H. B. Whitmore, R. J. Williams. *Women:* R. S. J. Baker, Mrs. H. F. Barner, J. E. G. Brieger, J. Chivers, F. M. Fountain, J. F. Grant, M. Hobson, P. A. Howard, E. G. Howe, G. M. Hunt, C. M. E. Jones, H. M. J. Lawn, B. M. Leach, G. A. Meigh, Mrs. M. H. Miller, Mrs. A. M. P. Pantin, A. M. Sibly.

R. Nigam, M.D., M.S.(Lucknow), has been appointed University Demonstrator in Anatomy, and J. A. R. Miles, M.B., B.Chir., and G. R. E. Naylor, M.B., B.Chir., have been appointed temporary University Demonstrators in Pathology, for three years from Oct. 1, 1946.

At a Congregation held on June 24 the following medical degrees were conferred:

M.D.—R. Daley, A. E. de la T. Mallett.
M.B., B.Chir.—C. H. Hoskyn, *G. S. Ostlere.

* By proxy.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—14 Margaret E. Bailey, 123B. N. Catchpole, 1D. A. N. Hoyte, 123D. Longson, 122J. Marshall, 1K. A. Rowley, Ruth A. Ainsworth, R. H. Broughton, W. B. Browne, D. A. Chadwick, C. P. Chivers, J. F. Cogan, J. K. Craie, Annie Cross, K. S. Daber, A. M. Davies, I. M. Gow, H. G. Herrmann, H. P. Hilditch, C. B. Hindley, D. P. Howarth, E. V. Hulse, E. Jaffe, P. D. Kelsall, 2P. B. Lacy, Theresa P. Lee, E. Levy, E. S. Lomas, Winifred M. McIlwrick, D. A. MacLeod, N. S. Moores, J. A. Noblett, M. Panikkar, I. W. Payne, E. Priestley, D. W. Purser, Anne R. Quinn, R. G. Rooney, V. E. Sherburn, K. D. Stewart, Roberta A. Stewart, 2J. B. L. Taylor, J. H. M. Thomas, Hilary M. Thompson, H. W. Wyllie. *Part I (Forensic Medicine and Hygiene and Preventive Medicine):* Mary K. Astin, Margaret Bagshaw, M. S. Barnett, Mary L. Barrett, K. Benger, Kathleen Burn, D. L. Chadwick, Elizabeth H. Clow, A. Coady, P. J. C. Davies, L. Dawson, J. Dubberley, R. D. P. Eaton, M. B. Feingold, J. R. C. Flett, P. D. Fowler, Ruth Good, J. Hampson (née Gannon), Thelma B. Hoyle, A. K. Karfoot, R. A. Kershaw, N. P. Lancaster, W. Lees, D. C. Lindars, Muriel Lister, G. P. Love, H. G. Lowe, V. T. Mason, J. G. Mathie, H. L. Matthews, I. O. Miller, C. L. Moss, G. N. L. Mulliner, A. Murphy, J. Naginton, J. A. Nightingale, L. M. Norburn, Mrs. Barbara Oldham, R. Ormerod, F. A. Rainford, J. Rimington, K. Robinson, A. E. Shelswell, Margaret E. R. Stoneman, D. B. Stott, Margaret E. Thorpe, J. T. L. Unsworth, Joan M. Waterfall, G. W. Waters, R. J. A. Webb, H. W. Wilson, Letitia E. Woodvine, D. H. Wright.

1 Second-class honours. 2 Distinction in Medicine. 3 Distinction in Surgery. 4 Distinction in Obstetrics. 5 Distinction in Forensic Medicine.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—H. Cantor, Eva V. Cooper, J. B. Hannah.
Ch.M.—W. R. Hunter, R. A. C. Owen.
M.B., Ch.B.—*Part III:* G. H. Daglish, Joan Evans, R. L. Goldson, Ailsa M. Heath, Vivien P. Helme, Maureen M. Hoey, D. T. L. Hughes, G. C. Hunter, H. S. Levy, F. W. Sheffield, Dorothy E. M. Thomas, Maureen M. Tickle, E. H. Wilson. *Passed in Separate Subjects:* G. B. Brown (Medicine and Surgery), P. Hampson and L. Robinson (Medicine and Obstetrics and Gynaecology), Nellie Hughes (Surgery and Obstetrics and Gynaecology). *Part II:* G. Frew, M. F. Holt, P. F. Jack, A. B. Jones, H. Keidan, G. H. Lucas, W. A. L. Thompson, W. P. Wilson. *Part I:* C. Alexander, C. E. Arkle, June P. Arnold, N. O. Ascroft, W. B. Ashby, D. J. B. Ashley, Barbara B. Ball, J. F. Bell, G. Bilsbarrow, Joyce L. Blakeley, L. B. Bruce, Anthea M. Bushby, 2 C. R. Cartwright, A. Dalzell, F. J. Dunn, E. C. Edwards, J. D. E. Edwards, J. A. Finnigan, G. Frew, H. L. Goffman, T. D. H. Gray, E. Gruber, Sylvia S. C. Hinde, C. I. Hood, A. W. Howell-Evans, Gwen E. Hughes, T. J. M. Hughes, J. Humphreys, Mair Humphreys, P. F. Jack, Dorothy M. Jennings, Elizabeth M. Johnson, C. Jones, C. H. Jones, W. W. Jones, Gwyneth H. Kendrick, P. Kilburn, Christine Lewis, 1 J. F. Lynch, A. G. MacKinnon, Mary K. Marchant, G. Marsh, E. Martindale, Margaret J. Miller, 12 Helen T. Morgan, E. G. Myerseough, J. O'Donoghue, Mary G. O'Hare, N. C. W. Owen, W. R. Parkes, W. H. Parry, Leslie M. Pinkerton, Gwyneth E. Pritchard, Freda M. Roberts, J. R. Roberts, R. V. Roberts, 2 Kathleen M. Roby, Barbara F. M. Shirley, H. M. Thomas, Joyce K. Watkin, 2 W. K. M. C. Watkins, D. B. Wilkinson, D. P. C. Williams, 12 H. T. G. Williams, W. P. Wilson. *Passed in Separate Subjects:* A. J. Bathurst and J. H. Murray (Pharmacology and General Therapeutics), J. N. Rimmer (Pathology and Bacteriology).
D.P.H.—*Part II (New Regulations):* G. P. Barclay, P. L. Bernard, T. B. D'Costa, E. C. Dymond, Thelma R. Gaunt, Eirwen M. Jones, A. E. Roberts, J. H. M. Tilley, Gwendoline Williams, W. R. Williams. *Old Regulations:* H. R. G. Davies.

1 Distinction in Pathology and Bacteriology. 2 Distinction in Pharmacology and General Therapeutics.

UNIVERSITY OF EDINBURGH

At a graduation ceremony, held on June 28, the honorary degree of LL.D. was conferred on Dr. John W. Bone, treasurer of the General Medical Council and of the British Medical Association, and Mr. J. W. Struthers, consulting surgeon to the Edinburgh Royal Infirmary and past-president of the Royal College of Surgeons of Edinburgh; also on Prof. Frédéric Joliot and Madame Irène Joliot-Curie, and on Mrs. Lilian Lindsay, honorary librarian and president of the British Dental Association.

UNIVERSITY OF ST. ANDREWS

The following candidates have been approved at the examinations indicated:

M.D.—*H. A. Haxton, J. D. B. Macdougall, *G. H. Smith.
M.B., Ch.B.—*J. W. Black, *R. M. Allan, *D. A. McGreal, *Marjorie S. Millin, *Mary I. Milne, *H. G. Morgan, *Valerie N. Naim, *W. F. Ross, *I. M. Stewart, *W. F. Walker, Joan E. Alexander, Maryan G. Anderson, Marjory W. Bervick, Doreen M. Bottonne, Katerina Bramley, Jean F. Brown, Laetitia M. Bruce, D. W. K. Buchanan, Athene M. A. Cochrane, Joan E. Cozens, J. M. Dunbar, Margaret Duncan, R. M. Duncan, G. Fyfe, Kathleen M. Graham, Anne E. Grant, W. G. Hood, Olive M. J. Johnston, M. A. Lambert, D. A. Lewtas, W. Lothian, C. E. MacDonald, H. MacKenzie, F. McKerracher, J. N. MacLennan, H. S. McWalter, A. C. Millar, Anne D. Miller, Elsie Morison, Sheila M. P. Morphy, Rhoda G. Nicoll, Alison Oberlin-Harris, Elizabeth J. Page, T. J. Parkinson, D. A. Petrie, Sheila M. Ross, S. A. Smith, Sheila M. Tocher, J. C. Walker, Charlotte J. S. White, S. Whitfield, Clare E. Wildeboer, Frances M. E. Wylde.

* With commendation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

On July 4 three Fellows were elected into the Council to fill the vacancies caused by the death of Sir Girling Ball and the retirement in rotation of Mr. Victor Bonney and Mr. Ernest Finch. The following Fellows were elected for the period of eight years:

Ernest Frederick Finch (Royal Infirmary, Sheffield) ..	625
Robert Paul Scott Mason, M.C. (Birmingham United Hospital) ..	379
Julian Taylor, O.B.E. (University College Hospital) ..	364

The following were the other candidates:

Ronald Ogier Ward, O.B.E., D.S.O., M.C. (St. Peter's Hospital) ..	356
Arthur Lawrence Abel (Princess Beatrice Hospital) ..	341
Rodney Honor Maingot (Royal Free Hospital) ..	288
Grant Massie, C.B.E. (Guy's Hospital) ..	276
Arthur Espie Porritt, C.B.E. (St. Mary's Hospital) ..	276
John Basil Hume (St. Bartholomew's Hospital) ..	262
Sir Stanford Cade, K.B.E., C.B. (Westminster Hospital) ..	204
Harold Clifford Edwards, C.B.E. (King's College Hospital) ..	196
William Hugh Cowie Romanis (St. Thomas's Hospital) ..	187
Norman Claudius Lake (Charing Cross Hospital) ..	166
William John Ferguson (West Middlesex Hospital) ..	94

In all 1,484 voted; in addition 12 votes were found to be invalid.

At the request of the Ministry of Health and Local Government of Northern Ireland; the Central Council for Health Education has established an area office in Belfast so that the work it undertakes on behalf of Government Departments and local authorities will now include Northern Ireland as well as England and Wales.

No. 25

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* an increased incidence was recorded for most infectious diseases; the rises included whooping-cough 401, measles 101, and scarlet fever 75. The only large decline in notifications was dysentery 53.

The increase in whooping-cough was mainly confined to the north, the largest increases being Lancashire 85, Yorkshire West Riding 48, Staffordshire 47, and Derbyshire 38. The only large fall was in Essex, where 34 fewer cases were notified than in the preceding week.

The largest rises in measles were Cheshire 76, Warwickshire 53. Scarlet fever increased slightly in most areas, and notably in Staffordshire 26 and Middlesex 21.

Last week's record low level of diphtheria increased by 12; the only large local variation was a rise in Staffordshire 12.

Returns for dysentery were the lowest for two and a half years. Only one county, Lancashire 35, had more than 10 cases.

In *Scotland* the largest variations in the trends of infectious diseases were a decrease in measles 120, scarlet fever 14, and dysentery 12, with an increase of 32 in acute primary pneumonia. Although the total for diphtheria remained unchanged a rise of 15 occurred in Glasgow. The largest returns for dysentery were Edinburgh 14 and Glasgow 10.

In *Eire* the chief feature of the returns was an increase of 26 in diarrhoea and enteritis. The largest returns were Dublin C.B. 33 and Waterford C.B. 10.

In *Northern Ireland* a decrease was recorded for measles 13 and scarlet fever 5, while an increase was reported for whooping-cough 7.

Week Ending June 29

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,063, whooping-cough 2,073, diphtheria 313, measles 4,177, acute pneumonia 440, cerebrospinal fever 39, dysentery 123, paratyphoid 9, typhoid 6.

Medical News

The twenty-third annual meeting of the Mental Hospitals Association is being held to-day, Friday, July 12, at 11 a.m. in the Guildhall, London. The programme includes a paper by Dr. Thomas Beaton, physician-superintendent of St. James Hospital, Portsmouth, on the National Health Service in relation to mental health.

The final programme has now been issued for the 105th annual meeting of the Royal Medico-Psychological Association to be held in Edinburgh on July 17, 18, and 19 at the Royal College of Physicians, 9, Queen Street. After election of officers and transaction of business at the first morning session, with Lieut.-Col. A. A. W. Petrie in the chair, Prof. D. K. Henderson will be inducted to the office of president at 2 p.m. and give his presidential address. On July 18, at 10 a.m., papers will be read on education in relation to psychiatry, and at 2 p.m. on the legal aspects of psychiatry. On July 19, at 10 a.m., there will be papers on the social aspect of psychiatry.

A provincial meeting of the Tuberculosis Association will be held at Oxford on July 18-20 in the Sir William Dunn School of Pathology, South Parks Road. On Thursday, July 18, at 2 p.m., Dr. F. R. G. Heaf and Dr. Donald Stewart will open a discussion on "The Tuberculosis in Industry," and Dr. William H. Feldman, of the Mayo Foundation, will read a paper on "streptomycin in experimental tuberculosis" at 5.15. On Friday morning Dr. Hans Jacob Ustvedt, of Oslo, and Dr. S. Roodhouse Gloyne will open a discussion on the relationship between primary and adult pulmonary tuberculosis. In the afternoon there will be papers and demonstrations on sarcoidosis. On Saturday morning Dr. André Bernou, of Chateaubriant, and Dr. Carl Semb, of Oslo, will open a discussion on the treatment of tension cavities.

The President and Council of the Royal Institute of Public Health and Hygiene have arranged a ceremony at 23, Portland Place, W., on Monday, July 22, for the presentation of the Harben medal to Sir Alexander Fleming, and the Smith Award to Dr. John J. Buchan. Guests will be received at 3 o'clock by the Right Hon. Walter Elliot.

The British Social Hygiene Council, Tavistock House North, Tavistock Square, W.C.1, will hold a summer school in social biology at Wadham College, Oxford, from Aug. 1 to 15. The fee is £13 15s. plus £1 1s. enrolment fee (not returnable). Applications and inquiries should be addressed to the Secretary of the Council in London.

At a meeting of the directors of the Society for Relief of Widows and Orphans of Medical Men, held on July 3, with Dr. A. Ware, senior, vice-president, in the chair, the death of a member was reported, also that of one of the widows, who had been in receipt of relief for 35 years and who was 83 when she died. She had received in grants from the society on behalf of herself and her two children the sum of £2,475. £1,937 10s. was voted for the payment of the half-yearly grants to the 53 widows entitled to them. Every Service member is requested to communicate with the secretary on demobilization and give his present address. This is very important, as until their arrears of subscriptions are paid they are not considered members of the society. Relief is granted only to widows and orphans of deceased members. Membership is open to any registered medical man who, at the time of his election, is residing within a twenty-mile radius of Charing Cross. Full particulars may be obtained from the secretary, 11, Chandos Street, Cavendish Square, W.1.

In June, 1945, a research unit was set up by the Medical Research Council and the Ministry of Fuel and Power to investigate the problem of Pneumoconiosis in South Wales. During the past year it has been expanding and starting various lines of work, including: (1) A study of disabled miners in order to discover the most suitable types of employment for them after leaving the pits; (2) An investigation into methods of treatment, for which purpose a ward has been set aside at Llandough Hospital by Cardiff City Council; (3) A long-term study of working miners and the air they breathe to make certain that methods of dust suppression are adequate to prevent the disease developing in the future; (4) An attempt to discover improved methods of detecting the disease in its earliest stage before the lung is permanently damaged. The research unit was opened officially on June 25, 1946, by H.R.H. the Duchess of Kent.

The Scottish National Blood Transfusion Association has appointed Dr. Douglas A. C. McRae as director of the Edinburgh and South-East of Scotland Blood Transfusion Service and of the Association's Central Depot (Eastern Area) at Edinburgh, in succession to Dr. C. P. Stewart, who has held these posts in an honorary capacity for several years. Dr. John Wallace has been appointed director of the Glasgow and West of Scotland Blood Transfusion Service, and of the Association's Central Depot (Western Area) at Glasgow, in succession to Prof. J. P. Todd, Ph.D., who has acted in an honorary capacity for several years. Dr. Stewart and Prof. Todd will continue their association with the work as honorary consultant directors.

Higher salaries for midwives have been agreed by the Rushcliffe Midwives Salaries Committee, and the new scales have been accepted. Mr. Aneurin Bevan, Minister of Health, who will recommend their adoption to all employing authorities. The increased salaries, which will have effect from Jan. 1 last, cover midwifery teachers, departmental midwifery sisters, midwifery sisters, and staff midwives working in hospitals and maternity homes, non-resident domiciliary midwives, and pupil-midwives. Higher payment is also recommended for midwives giving part-time service.

The appointment of Dr. Peter Reid, of Buckie, Banffshire, as chief medical officer to the U.N.R.R.A. Mission, Czechoslovakia, is announced. Dr. Reid has been in the R.A.M.C. since the outbreak of war in 1939, from which he has been released to take up this appointment. Previously Dr. Reid had spent many years in Peru as chief medical officer to the oilfields there, and in 1932 he went on to a similar position as chief medical officer at Basrah, Iraq.

The National Association for the Prevention of Tuberculosis, which has already conducted medico-social surveys on tuberculosis in various parts of the British Commonwealth, is now undertaking, in co-operation with the Government of the Gold Coast, a survey of the problem in that Colony. A Research Fellow, who will be a specialist doctor and have a technical assistant, is to be appointed to conduct a twelve-months medico-social survey, and the N.A.P.T. will publish a report of his findings.

Announcement is made by Surgeon General Thomas Parran of the U.S. Public Health Service that a grant for the establishment of 125 Fellowships to train American physicians and sanitary engineers in public health has been approved by the National Foundation for Infantile Paralysis. Each Fellowship provides a year's graduate training in a school of public health or a school of sanitary engineering.

Six senior administrators of the Greek nursing services are visiting Britain under the auspices of the British Council and the Royal College of Nursing to learn of nursing and hospital developments and meet British colleagues. In London they will visit the Peckham Health Centre, the Florence Nightingale International Foundation hospitals, and nursing organizations.

The new *Register of Speech Therapists* has been published by the Board of Registration of Medical Auxiliaries, and medical practitioners can obtain a copy free on application to the Registrar of the Board, B.M.A. House, Tavistock Square, London, W.C.1.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Airborne Cardiac Case

Q.—A patient, aged 49, has an enlarged heart with aortic and mitral valvular disease due to old rheumatism. She gets about quite well and leads an active social life. Should she be allowed to travel by air to Switzerland—a journey of four hours at between 2,000 and 5,000 feet?

A.—At high altitudes the pressure of oxygen in the inspired air is less than normal. The work of the heart in supplying the tissues with an adequate quantity of oxygen is correspondingly increased. It is generally held that altitudes up to 5,000 feet (1,500 m.) increase very little the burden on the heart. In the case under consideration, although heart disease is well developed, there is obviously a reasonable cardiac reserve as the patient leads an active social life. It may be predicted, therefore, that this individual will tolerate the journey of four hours at an altitude not exceeding 5,000 feet without distress at the time or undesirable after effects. It has to be borne in mind that other factors come into play, such as the temperament. A neurotic or highly strung disposition would facilitate the development of symptoms from minor causes, but would be hardly likely to represent a serious hazard in the present instance.

Quick Twins

Q.—A young woman is due to have her second confinement in four months' time. She says she knows she is going to have twins because (a) her husband is a twin, (b) her own sister has had twins, (c) she feels no movements and has been told that this is a sign of twins. Is there anything in the belief that lack of quickening is a sign of twins?

A.—I have never previously heard of this belief, although it may well appear in the older writings and some reader can perhaps supply a reference. The idea may have arisen as the result of the association of multiple pregnancy and hydramnios. In the latter condition the patient is sometimes unconscious of foetal movement. The more common view is the opposite—i.e., that excessive foetal movement is a sign of twins, and this undoubtedly is sometimes true. In this case the strong family history of twins is more significant than anything else. It should be added that a large proportion of women think that their second pregnancy is multiple. This is because they feel "larger" than they did in the first pregnancy, because the tone of the abdominal and uterine muscles has deteriorated, and they are more conscious of foetal movements.

Progressive Muscular Atrophy

Q.—Has the cause of progressive muscular atrophy been discovered? What treatment is possible in a case intolerant to atropine? What is the prognosis?

A.—The cause of true progressive muscular atrophy has not yet been discovered. In view of a somewhat similar picture arising at times in association with neurosyphilis, an examination of the cerebrospinal fluid and of the blood Wassermann should be done. There is no form of treatment known which has the slightest effect. Drugs of the atropine class are used only for

their effect in diminishing secretions where bulbar symptoms raise a risk of inhalation pneumonia; they are not necessary otherwise in uncomplicated cases of progressive muscular atrophy. The duration of life varies from a few months to a few years, the average being two years. Cases with bulbar involvement run a shorter course.

Chronic Pancreatitis

Q.—What is the best treatment for chronic pancreatitis?

A.—Chronic pancreatitis may cause symptoms either as a result of inflammatory and obstructive lesions or by defective production of enzymes governing protein and fat digestion and absorption and carbohydrate utilization, as well as other functions not yet elucidated. Treatment of the first type is surgical and should eliminate factors such as infection and stones from the gall-bladder and common duct; treat symptomatically the recurrent attacks of abdominal pain. In the second group, since cases have been recorded of patients with no symptoms save for loose stools, though necropsy has shown almost complete replacement of pancreatic tissue by fat, no therapy may be needed. However, between such patients and those who go downhill rapidly with severe upsets in protein, fat, and carbohydrate metabolism all varieties of defect may be encountered.

Successful substitution therapy with pancreatic extracts effects improvement in both fat and protein absorption (Rekers, Pack, and Rhoads¹; Beazell, Schmidt, and Ivy²). Unfortunately, commercial preparations have varied in activity, so it is important to give adequate and effective doses—at least 5 g., and in some cases up to 20 g., daily in enteric-coated capsules by mouth—to ensure benefit. Much of the abdominal discomfort and diarrhoea can be controlled by a high-protein, low-fat diet. If steatorrhoea is present, advantage should be taken of the extra meat allowed under the present rationing scheme. A high-fat diet, although increasing the actual amount of fat absorbed, leads to an exacerbation of the abdominal symptoms. The diabetes sometimes associated with chronic pancreatitis should be controlled with insulin. Finally, upsets of liver function have been demonstrated and a lipotropic effect of certain pancreatic extracts claimed. The significance of these observations is not yet fully understood, and no therapy which can be recommended for routine use is, as yet, available.

Sulphur Dermatitis

Q.—I recently treated a case of scabies with a proprietary ointment containing sulphur. What is the treatment of sulphur dermatitis?

A.—Dermatitis from sulphur applications is very common, both from individual sensitivity to sulphur and as a result of direct irritation. The treatment is to avoid sulphur internally or externally and any strong applications to the skin. The course depends upon the extent of the trouble and the type and health of the patient. For mild cases advise baths followed by calamine lotion or liniment. For more severe cases Lassar's paste diluted with an equal quantity of soft paraffin. Rest, alkalis, and mild sedatives are of value.

Schick Test and Pseudo-reactions

Q.—Our local health authorities are using the Schick test without a control. Is this the recognized practice nowadays?

A.—The Schick test is commonly used for two main purposes: (1) to test the susceptibility of a child or a community to diphtheria, and (2) to test the efficacy of artificial immunization—sometimes called the Schick-conversion rate. If in a community where the test is being used as an index of susceptibility there are older children, some of whom will probably give pseudo-reactions, the control material should always be used, for the severe local or systemic upsets which sometimes follow the injection of the prophylactic reagent occur most often among these pseudo-reactors. It is wiser not to give them any injection. If on the other hand the Schick test is being used to check the efficiency of a particular method of immunization in a group of young children, the control test need not be used since we are not concerned with the occurrence of pseudo-reactions.

Phytic Acid and Osteo-arthritis

Q.—If phytic acid stops the absorption of calcium (May 18, p. 784), would not foods containing it be of service in hypertrophic osteo-arthritis?

A.—No. The primary lesion in osteo-arthritis is erosion and fragmentation of articular cartilage. The hypertrophic bony changes are an attempt to replace a damaged joint surface. There is no increase in the serum calcium in osteo-arthritis and to cause decalcification by any method in this condition might lead to osteoporotic changes in the affected joints, such as are found in rheumatoid arthritis. Decalcification might also cause the serious general effects of a low serum calcium level.

Blood Pressure and Emotion

Q.—Do nervous and neurotic states influence the blood pressure?

A.—From everyday experience it is known that the blood pressure responds easily to emotional stimulation. Fahrenkamp demonstrated that in hypertensive patients the level of blood pressure is subject to considerable fluctuations according to their emotional state. Knauer observed in soldiers with healthy blood vessels increases in blood pressure, up to 180 mm. Hg, immediately after a fierce bombardment; this increase subsided only after a few days' rest in hospital. As a result of their systematic investigations, Dunbar, Alexander, and Saul came to the conclusion that the common characteristic of hypertensive patients is their inability to deal with their aggressive impulses. They are friendly and easy to get on with in their social contacts, but repression of hostility which is near to the surface leads to anxiety, which, in turn, finds expression in hyperpiesis. Dunbar draws attention to the increased tension, and sometimes spasm, of voluntary or involuntary muscles, or both, commonly encountered in hypertensive patients, which may be alleviated as unconscious conflicts become conscious. She feels that this tension is part of the whole defence mechanism psychologically and physiologically—a general attitude of being on guard. Psychological treatment of selected patients suffering from hypertension was strikingly successful.

INCOME TAX

Employee "Living In"

B. S. employs a secretary-dispenser and in addition to paying him a salary provides him with board and lodging—computed "to be worth £3 a week." Can B. S. deduct £3 a week as a professional expense?

•• Yes—with the proviso that the amount should represent the cost to B. S., not necessarily the amount which the board and lodging is "worth" to the employee.

Temporary Residence in the United Kingdom

"MATA" expects to come to the United Kingdom in the autumn for a course of special study. Will the date of his arrival affect his income tax liability?

•• Yes. Although he is coming for a temporary purpose only he will be liable as if resident here for any financial year in which he spends six months in this country. If he arrives after Oct. 5, 1946, he will not be liable for 1945-6. If he arrives before Oct. 5 he will be so liable unless he absents himself from the United Kingdom for a period long enough to reduce his stay here before April 6, 1947, to a period less than six months.

Recoveries from Debts Written Off

"D." is partner in the firm of E. and D. The practice was formerly owned by B. and E., and outstanding debts were valued yearly and the income tax allowance accordingly received in respect of bad and doubtful debts. E. and D. bought the debts at a valuation (presumably that amount was the closing figure in B. and E.'s accounts) and have since recovered more than the aggregate paid for the debts. Is the excess liable to be brought into the accounts of E. and D. for income tax purposes?

•• It is assumed that E. and D. wish to be treated as continuing the practice, and not as commencing a new one. The validity of the general ruling of the Revenue authorities (i.e., that the amounts recovered in excess of the net amount that have been credited for income tax purposes shall be brought in as income) was recently supported by a decision of the Court of Appeal, and any objection "D." might raise on appeal against the decision of the Inspector

of taxes would accordingly fail. If, on the other hand, the firm of E. and D. should elect to be charged to income tax, as if they had commenced a new practice, the basis of the decision would not seem to apply, and it might be possible to exclude receipts in question. But, of course, other factors would have to be taken into account before it was decided to make such an election.

Car Transactions

F. E. bought a car "V" in 1939 for £200 and has been allowed £170 depreciation on it. It was sold on March 26, 1946, for £280, showing a capital profit of £260—(£200—£170=) £30—i.e., £250. Car "S" was bought for £505 on March 12, 1946, and taken over on March 25, 1946.

** No "balancing charge" is due on car "V" as it was sold before April 6, 1946. Claims should be made in respect of car "S" for 1947-8 as follows:

Initial allowance	£50 @ 20%	£ 01
Wear and tear	£505 @ 25%	£125
				<u>£227</u>

The capital value to carry forward for the 1948-9 allowance will be £505—£227=£278.

"EQUITY" bought a car "A" in 1939 for £200 and has received wear and tear allowances on it amounting to £132. (A further £17 will be allowed on it for 1947-8, reducing the value to £51) He sold it on April 8, 1946 for £560, and on the same day bought car "B" for £703. How is his liability affected?

** The transactions do not affect the tax for the years 1946-7 and 1947-8. For 1948-9, however, "EQUITY" will be liable on a balancing charge of £560—£51=£509, and can claim in respect of car "B" the initial allowance (20% of £703=£141) and the wear and tear allowance (25% of £703=£176).

A. R., who is in general practice, bought a new car on March 5, 1946, for £614, selling his old car for £250.

** For the purposes of the initial allowance the car will be deemed to have been purchased on April 6, 1946—this is in accordance with the Income Tax Act, 1945. Consequently the initial allowance will be due for 1947-8 not for 1946-7. If the accounts of the practice are made up to a date not earlier than March 5, depreciation allowance—i.e., 25% of £614—can be claimed for 1946-7, but if the accounts are made up to, say, Dec. 31, the depreciation allowance for 1946-7 will not be affected, though it will be, of course, for 1947-8.

P. J. will practise as a locum tenent from Aug. 1 to Sept. 30 and will buy a car for £500 in August. On Oct. 1 he will become a partner in an existing practice.

** Assuming that it is necessary for P. J. to have a car to perform his duties as a locum tenent he will be entitled to set against his earnings in that capacity the initial allowance on the car—i.e., 20% of £500=£100 and wear and tear at 25% of £500=£125 for two months—i.e., £21. The practice is presumably assessed on the basis of the previous year, and P. J. will be liable for tax on his share of that assessment. That tax will accordingly not be affected by the purchase of the car in the current year.

Cash Basis or Earnings Basis

"DEMOBBED" returned in May, 1945, to a practice which was carried on for him in his absence. Income tax was assessed for that period on the basis of the cash received. Can he make his return for 1945-6 on the basis of the cash received in 1944-5, and his return for 1946-7 on the basis of the cash received in 1945-6?

** We advise him to do so. This is not a case of a practice having ceased and been restarted: it was carried on as a continuing practice, though for a time necessarily in a different manner. "DEMOBBED" and the Revenue authorities both applied the cash basis on those lines, and no doubt hitherto to the detriment of the former. Law and equity both justify the continuance of the cash basis for the years subsequent to demobilization.

Schedule E Car Expenses

W. S. receives a car allowance of £150 per annum as a whole-time M.O.H. Can he claim as an expense the excess of his expenditure (plus depreciation, etc., allowances) over the £150 received?

** He is so entitled in law provided that he can prove the expenses to be "necessary" in the performance of his duties. But he will no doubt find it difficult to show to the satisfaction of the appeal commissioners that the Local Authority does not pay an allowance large enough, taking one year with another, to meet the "necessary" expense.

LETTERS, NOTES, ETC.

Treatment of Sterility in Women

Mr. TERENCE ROBINSON (South Shields) writes: Many cases of infertility are relieved by curing a cervical erosion, which has been produced often by the use of vaginal tampons during menstruation. This highly unphysiological practice is increasing along with the cult of douching the vagina with various chemicals. The advertisements of the vendors suggest that the vaginal douche should form part of the normal toilet. If this were desirable, Nature in her wisdom would have arranged, no doubt, for the urinary meatus to emerge in the anterior fornix. In conclusion I would plead for the substitution of "infertility" for "sterility." Although both words mean the same, infertility does not suggest the complete barrenness and lack of life associated to-day with "sterile." The diagnosis could be altered to sterility in the final summing-up after the menopause.

Intractable Major Epilepsy Controlled by "Epanutin" and "Luminal"

Dr. T. G. BAYLE (London, W.13) writes: A girl aged 16 first came under my care in January, 1946. She had a history of major epileptic attacks extending back four years. The attacks occurred during the day and numbered 7 to 10 a week. She had been treated with bromides and phenobarbitone without effect. A few years ago an attempt was made to control the attacks with "epanutin" (sodium diphenylhydantoinate). This was discontinued as the patient developed suicidal tendencies, and she was returned to "luminal" gr. 1 thrice daily. Her attacks continued to be 7 to 10 weekly, all occurring in the daytime. On consideration I decided that this was a case which might be benefited by treatment with epanutin and luminal, and I put her on epanutin gr. 1½ and luminal gr. 1/2 twice daily after food. She was free for a month but then had an attack at the menstrual period. After this attack in February, 1946, I put her on epanutin gr. 1½ thrice daily after food, with luminal gr. 1/2 twice daily—i.e., gr. 1/2 morning and gr. 1/2 at night. Since then she has remained free from all attacks. She was dull and apathetic whilst on luminal. Under present treatment she is bright and cheerful, has regained complete confidence, and has taken up an office job. She is entirely free from toxic and psychotic effects. This is an example of the type of case which may benefit by treatment with epanutin, which of course should not be instituted until more usual methods have failed. The control of the severe psychotic effects resulting from its combination with so small a dose of phenobarbitone as gr. 1/2 twice daily is worthy of note.

Bread Rations for Doctors

Dr. T. E. SEYMOUR LLOYD (Luton) writes: The Government's proposed scheme for bread and flour rationing overlooks the claim to an increased ration of a hard-working and vitally important section of the community—namely, the medical profession. In actual expenditure of energy, doctors by virtue of their long hours of work and mental strain undoubtedly exceed many classes of manual workers. If corroboration is required, reference may be made to the findings of the Spens Committee. The coming winter promises to be a time of great hardship for the community with its overcrowding due to housing shortage, insufficient warmth, and inadequate dietary, which in small families may approach starvation level. In consequence a deterioration in the nation's health with increased sickness is probable, which will further overtax the doctors, who, if they are to function efficiently as guardians of the health of the community, must be guaranteed a minimum diet consistent with their caloric requirements. I urge, therefore, that the medical profession should make strong representation to the Government that, on grounds of vital necessity, active members of the profession should, in view of the arduous nature of their work, receive the same bread and flour ration as manual workers.

Sir William Macewen

Mr. D. LIGAT, F.R.C.S., writes from St. Leonards-on-Sea: When I was dressing for the late Sir Alfred Pearce Gould, I asked him who he thought was the greatest surgeon of the century. He said without hesitation, "Kocher or Macewen, and I think Macewen just has it."

Corrigendum

The authors of "A Short Survey of Trilene in General Practice" (July 6, p. 10) wish to make the following corrections: (1) The heading to Table II should read: "Results with Trilene (All Cases)." (2) Table III should be headed: "Midwifery: Extended Analysis Table II (Selected)"; and "Cases" should be substituted for the word "Cases" at the top of its second column. (3) The second line of the subheading "midwifery" on p. 12 should have been: "In less than 20% of cases complete amnesia followed its use."

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 13 1946

British Medical Association

ANNUAL REPRESENTATIVE MEETING, 1946 ADDITIONAL RESOLUTIONS BY DIVISIONS AND BRANCHES

Report of Agenda Committee

Motion by WINCHESTER: That this meeting be informed what action has been taken in connexion with Minute 11 of the S.R.M. of May 1, 1946, and what method is being adopted to deal with the congestion of business at Representative Meetings.

PRELIMINARY

Ex-Service Practitioners

Motion by WESTMINSTER AND HOLBORN: That this meeting considers that steps should be taken to cause the appropriate authority to be empowered to give some assistance to practitioners leaving the Services to acquire premises which may be used as surgeries.

NATIONAL HEALTH SERVICE

Motion by SWINDON: That in view of the imminent threat to the traditions and freedom of the profession contained in the proposed National Health Service Bill this meeting proposes that a suitable covenant be drawn up by the Association and signed by all medical men as a guarantee of unity.

Motion by WESTMINSTER AND HOLBORN: That this meeting is of opinion that in the future National Health Service the extent of certification should be strictly defined and adhered to, that special payment should be made for this service, and that if certification is extended additional payment should be made.

Motion by WESTMINSTER AND HOLBORN: That the Association set up an Advisory Committee to advise doctors on the sale and value of practices prior to the introduction of the State Medical Service, and the position of members of partnerships after this event.

Motion by BOURNEMOUTH: That for the safeguarding of private practice, whether general or special, an essential is the preservation of independent private nursing institutions apart from the hospitals, and there should be no power vested in the Minister under a National Health Service Act to acquire such institutions without the consent of the owners, nor power to prevent the establishment of such institutions.

Motion by MERIONETHSHIRE AND MONTGOMERYSHIRE: That this meeting urges the Council to emphasize in all negotiations with the Government the extreme importance of adequate mileage payment to practitioners in mountainous areas with a sparse and scattered population.

Motion by WESTMINSTER AND HOLBORN: That it shall be provided in the terms and conditions of service under the National Health Service that any accusation against a medical officer employed by a local health authority for the purpose of procuring dismissal or reduction of status of that officer shall not be brought before the local authority in the absence of the officer without reasonable notice, or without giving him or her the opportunity to answer such accusation or criticism.

Motion by BROMLEY: That in the event of the goodwill of practices being acquired by the State and of compensation being paid, the practices of those doctors who were killed or disabled by enemy action during the war should rank for compensation on the basis of the 1939 income in those cases where the goodwill has not already been sold.

Motion by ISLE OF WIGHT: That local meetings of the profession be called immediately to draw up Terms and Conditions of Service which will be acceptable to the profession.

Motion by NORTH GLAMORGAN AND BRECKNOCK: That in the analysis of results of a referendum of the profession, due regard be taken to age, particularly with reference to purchase and sale of practices.

Motion by NORTH STAFFORDSHIRE: That, in view of the possibility of the National Health Service Bill in its final form being unacceptable to the profession, this meeting is of opinion that Council should take further steps towards decentralization of the Association by the provision of local organizers either medical or lay on a regional basis.

Motion by NORTH STAFFORDSHIRE: That in any future medical service the Council shall take steps to ensure that a suitable body be appointed on the lines of the Spens Committee or a Whitley Council to whom all differences between the profession and Government regarding remuneration can be referred.

NATIONAL HEALTH INSURANCE *Report of Spens Committee*

Motion by WESTMINSTER AND HOLBORN: That this meeting considers that the Association should press with the utmost energy for an increase in the capitation fee, such increase to be retrospective.

Motion by WESTMINSTER AND HOLBORN: That in any negotiations with the Minister the Association be represented by counsel to deal with legal points.

Motion by WINCHESTER: That this meeting instructs the Council—

(1) To demand an immediate increase in the N.H.I. Capitation Fee, with compensation to date back to the time when the B.M.A. first put forward its application for an increased rate.

(2) To re-establish confidence in the integrity of the State in its contracts with the medical profession, to demand compensation from the State for its previous unilateral breach of contract whereby the income level of those to be eligible for medical benefit was raised arbitrarily, to the prejudice of the general practitioner already underpaid for his N.H.I. services.

(3) That in any negotiations for capital repayment by the State regard must be had to the undervaluation of the goodwill due to this uneconomic N.H.I. capitation fee.

Motion by SOUTH-WEST ESSEX: That in view of the fact that the Spens Committee has now reported, an immediate increase in the capitation fee is demanded. Such increase should be retrospective to the date of inception of the Spens Committee.

Regional Medical Service

Amendment by HENDON: That the Representative Body is strongly opposed to the introduction of any machinery whereby the Regional Medical Officer may refer a patient to a specialist for a second opinion without affording the patient's own doctor an opportunity of selecting the consultant and effecting the necessary arrangements.

SPECIAL PRACTICE

Access to Ancillary Departments of Hospitals

Amendment by WEST SUFFOLK: That experience having shown that the advantage of the policy of the "open door" outweighs the disadvantages, it should be adopted as a uniform system throughout the country.

Status of Group Committees

Motion by WEST SUFFOLK: That, with reference to para. 50 of the Council's Report, local meetings of consultant and specialist groups should be open to all such consultants and specialists, whether whole or part-time.

Part-time Consultants and Specialists

Motion by ISLE OF WIGHT: That, whilst approving para. 51, this meeting requests Council to take the action passed by A.R.M., July, 1945 (Min. 71), in order to allay the present widespread apprehension.

(Minute 71 is as follows:

RESOLVED: That this A.R.M. requests Council to inform part-time consultants and specialists on hospital staffs what steps are being taken to safeguard their position and future employment.)

Examination of Pensioners referred to Specialists

Amendment by SWANSEA: That, with reference to the first section of para. 53, this meeting is of opinion that the fees paid by the Ministry of Pensions for cases referred to specialists should be £2 2s. for each of the first two cases, and £5 5s. for a session of two hours, with a maximum of three cases.

PUBLIC HEALTH

Salaries in the Public Health Service

Amendment by NORTH STAFFORDSHIRE: That this meeting urges that pressure be applied to obtain early agreement on revised Askwith scales and expresses the opinion that the interim adjustments are unsatisfactory.

National Maternity Service

Amendment by BRADFORD: That this meeting reaffirms the following Minute 127 of the A.R.M., 1945:

That, with reference to para. 32 of the Annual Report of Council, this Representative Body is determined to pledge itself to resist the introduction of any new criteria of qualification in midwifery that would, if officially recognized, deprive any registered medical practitioner of the right to practise midwifery in a National Service,

and submits the following rider:

That this meeting considers it irrational that a student should be instructed and qualified to practise in midwifery, and subsequently be refused permission to practise that subject without further instruction following qualification.

Amendment by HENDON: That the Council be instructed to oppose the introduction of new criteria of qualification sponsored by the Royal College of Obstetricians or the Ministry of Health, which would have the effect of precluding any competent general practitioner from engaging in the practice of midwifery among public or private patients, if and when he so desires.

Fees for Practitioners called in by Midwives

Motion by NORTH STAFFORDSHIRE: That this meeting is of opinion that the minimum fee for attending a full confinement under local authority arrangements should be £5 5s.

Motion by NORTH STAFFORDSHIRE: That in the opinion of this meeting the fee payable by a local authority for a full ante-natal examination and report should be £2 2s.

Doctors employed Part-time by Local Authorities

Amendment by HENDON: (i) That the fee for immunization at a doctor's surgery should be 5s. per injection; (ii) that the fee for visiting a child at home and giving injections there should be 7s. 6d. a visit.

Milk

Motion by ISLE OF WIGHT: That this meeting is of opinion that legislation should require that all milk sold to the public should be either pasteurized or from tubercle-free herds.

ORGANIZATION

Subsistence Allowance of Representatives attending Representative Meetings

Motion by LEEDS: That Representatives, members of Council, members of standing committees or other committees set up by Council be paid a subsistence allowance of £1 ls. per day or part of a day when attending the appropriate meetings of the Representative Body, the Council, the standing, and other committees.

Motion by NORTH GLAMORGAN AND BRECKNOCK: That Divisional Representatives be paid a subsistence allowance out of central funds when their attendance at Representative Meetings involves staying away from home.

Elections to Committees

Motion by SOUTH-WEST ESSEX: That in the future all nominations as candidates for elections to seats on committees which are voted upon by the A.R.M. should be published three weeks prior to that meeting.

NAVAL AND MILITARY

Demobilization

Motion by WESTMINSTER AND HOLBORN: That this meeting does not regard the release from the Services as satisfactory, and considers that establishments are overstaffed.

OTHER MOTIONS OF DIVISIONS AND BRANCHES

Bread Rationing

Motion by ISLE OF WIGHT: That in the opinion of this meeting doctors and nurses, owing to their long irregular hours and seven-day week, should be placed in a category which receives higher bread rations than sedentary workers.

PUBLIC RELATIONS

Motion by LINCOLN: That in view of the small amount of newspaper publicity given to B.M.A. opinion, advertising space should be used in the national press.

Motion by WESTMINSTER AND HOLBORN: That this meeting feels that relations with the Press are still not satisfactory.

HOSPITALS

"General Practitioner" Hospitals

Motion by GATESHEAD: That in any hospital area it is essential that facilities should be afforded general practitioners, either in

general practitioner or other hospitals, to attend their own maternity cases either privately or otherwise.

Motion by NORTH STAFFORDSHIRE: That the Association should demand the provision of general practitioner hospitals under any new Health Service Scheme.

Nursing and Domestic Staffs of Hospitals

Motion by WESTMINSTER AND HOLBORN: That, with reference to para. 22 of the Council's Report, this meeting views with anxiety the lack of nursing and domestic hospital staff, and considers that energetic steps should be taken to rectify it, and suggests that every inducement should be offered to those leaving the Services to continue in nursing.

GENERAL PRACTICE

Fees for Life Insurance Examination

Motion by CITY: That this meeting recommends that when a doctor is requested by an insurance company or a solicitor to be present at the examination of his patient by another doctor for the purpose of assessing a claim arising out of the patient's injury or illness the fee payable should be not less than £2 2s.

Private Practice under 100% National Health Service

Amendment by HENDON: That the patient who elects to obtain medical advice privately shall not be required to pay for drugs and appliances.

Amendment by ISLE OF WIGHT: That, with reference to para. 30 (2), the words "of his" be substituted for the words "of any partner or."

Amendment by ISLE OF WIGHT: That para. 30 (7) be referred back to Council.

Telephone Facilities for Doctors

Motion by WESTMINSTER AND HOLBORN: That this meeting is of opinion that representations should be made to the Postmaster-General that the telephone service should provide facilities at each exchange for taking messages during such times as a doctor may notify that his telephone will be unattended.

Post Office Medical Officers

Motion by HENDON: That the Council take steps to secure an increase of the visiting fee from 3s. 6d. to 5s. and the abolition of the over-riding quarterly maximum of 14s. paid by the Post Office to Post Office medical officers for attendance on postal employees living out of the district of their employment.

Coroners Act

Motion by HENDON: That the Council be invited to review and submit a report on the working of the Coroners Act since its introduction, paying special attention to the difficulties attendant upon pathological examinations, fees payable to medical practitioners as witnesses, and other difficulties experienced by the profession in carrying out the statutory and other directions of the coroner.

SALARIES OF WHOLE-TIME PUBLIC HEALTH
MEDICAL OFFICERS*Interim Revision of Askwith Memorandum*

Agreement has been reached between representatives of the British Medical Association and representatives of local authorities for an interim revision of the Askwith Agreement. At a conference at the Ministry of Health on March 26 the following were represented: County Councils Association; Association of Municipal Corporations; Urban District Councils Association; Rural District Councils Association; London County Council; Association of Education Committees; Mental Hospitals Association; Metropolitan Boroughs Standing Joint Committee.

In Circular 140/46 of July 4, it is pointed out that the interim revision has now been accepted by all parties to the Askwith Agreement, which came into force on April 1, 1930. The interim revision is being circulated to all local authorities by the Minister of Health. The Minister has been asked to make it clear that all parties accept the interim revision as embodying scales of salaries recognized as being appropriate to public health medical officers.

Details of the new recommendations correspond closely with the proposals put forward by the Council of the British Medical Association and recorded in the *Supplement* of April 20 (p. 93)

"SOCIAL MEDICINE" IN EAST AFRICA

In his recent presidential address to the Kenya Branch of the British Medical Association Dr. A. R. Paterson discussed what is described as the social function of the Association in East Africa—namely, to persuade both Government and people of the importance of a far greater measure of efficient medical service. The problems presented in connexion with health services in Kenya, he said, were not less difficult of solution than those in Great Britain, and to meet them, for 4,000,000 people, there were only about 150 doctors—one to 25,000 of the population, or, in many areas, one perhaps to 100,000. About a year ago in Kenya a Government committee on health, hospital services, and nutrition was appointed, and when it reported it was expected to recommend an extension of medical services with the provision of more medical staff. The question was how to obtain this staff by oversea recruitment, and for how long ahead and for what size of population the planning ought to take place.

Dr. Paterson mentioned that the Kikuyu, a tribe comprising one-fourth of the population of the colony, is increasing at the rate of not less than 2% per annum, that the physical condition of these people may be deteriorating, and that the agricultural congestion and pressure of population in Kikuyu lands are now so great that without some organization these lands may be on their way to becoming a desert during the next decade. Of the rest of the population there are no reliable census figures, but the Kavirondo peoples may well be increasing at the same rate. A "biological bomb" has exploded in this part of East Africa, and the capacity to organize or reorganize African society and raise its standards of living has to be measured against the tendency of native peoples to increase in numbers up to subsistence level at the poor standards which are the only ones they know.

The African Doctor

The coming on the scene of the African doctor made it necessary that he should be well trained, that he should be inspired with a fine tradition and an adequate conception of his vocation, and that there should be an effective organization or the distribution of such doctors and accompanying facilities. In South Africa a National Health Services Commission, appointed in 1942, has suggested a doctor-patient ratio rather higher than 1 to 2,500, and has stressed the importance of personal preventive health services based on the family as a unit, with periodical medical examinations and properly staffed health centres. To make provision on this scale in Kenya would require 1,500 doctors, most of them African. Makerere College is at present turning out only two or three African doctors a year for Kenya, but it is planning for extension, and the Colonial Development and Welfare Fund is expected to help; but local revenues will be required, both for the support of Makerere and for the provision of greatly increased primary and secondary education in local schools, without which there can never be enough entrants to Makerere.

The training of these new African doctors called for lecturers and medical practitioners from over-seas, the great majority of whom would be members of the B.M.A. Were they being prepared adequately and made familiar with the methods of practice of medicine appropriate to rural and urban Africa? Dr. Paterson thinks that few would answer that question in the affirmative. Here he quoted from the chapter on social medicine in the Goodenough report:

"There is growing support for the view," says the Goodenough report, "that a general medical practitioner should become the health adviser of his patients and their families and should participate to a greater extent in the conduct of the health services of the country. . . . The training which most students receive at the present time is not sufficiently directed to this end."

The practice of social medicine among Africans could clearly never be carried out by doctors working "on their own." The "social medicine doctor" would be concerned with families, a member of a team with district nurse, midwife, health visitor, health inspector, with provision for systematic records and liaison with social agencies, and with the support of hospitals well equipped and staffed.

A State Service Needed

Whatever might be the case elsewhere, in the great rural native areas of East Africa, in Dr. Paterson's view, only a State service would meet the situation. The key posts in such a service for many years to come must be filled by medical officers recruited from over-seas, and must be additional to the present establishment. These officers must be given the opportunity of becoming specialists in social medicine—specialists, so to speak, in general practice, but in general practice of a better and far more interesting kind than has been practicable hitherto.

At present the service in Kenya was so small as to preclude the specialization necessary to efficiency. In the promotion of a colonial health service of this kind Dr. Paterson foresaw a large part for the B.M.A.—first of all in placing the need for such a service before Government and people. Recently in Kenya there had been appointed to the Governor's Council a member responsible for advising the Governor on health matters and for the execution of his decisions. This meant recognition by the Government that the promotion of public health must always be an object of Government policy, and it furnished the Association in Kenya with a channel through which to transmit to the Government its representations with the certainty that they would receive informed consideration.

MEDICAL WAR RELIEF FUND

SEVENTY-SIXTH LIST

Individual Contributions

- £395 4s. 6d.—Legacy from the late Dr. G. H. Foott, Southampton.
 £100.—Mr. H. Dodd, London (2nd donation)
 £52 10s.—Mr. W. H. Hey, Stockport.
 £50.—Anonymous.
 £26 5s.—Drs. Grose and Stevenson, Edgware.
 £25.—Dr. A. Beauchamp, Birmingham (2nd donation); Dr. John T. Ingram, Leeds (4th donation); Dr. M. K. and Mrs. Robertson, Oxford (5th donation).
 £21.—Dr. C. R. Selwyn Jones, Chard (2nd donation).
 £20.—Mrs. S. M. V. Richardson, Cbellenham (3rd donation).
 £15 15s.—Anonymous.
 £10 10s.—Dr. Barbara Abercromby, Liverpool (2nd donation); Dr. Madeline Giles, Harrow (2nd donation); Mr. R. Jaques, Worthing (3rd donation); Mr. A. Martin-Leake, Ware (2nd donation); Dr. H. B. Pierce, Mountain Ash (2nd donation); Dr. W. H. Steele, Newton Abbot (8th donation); Dr. T. J. T. Wilmot, Louth (3rd donation).
 £10.—Dr. W. L. Blakemore, Staines (5th donation); Dr. A. E. Ironside, Ashted; Lieut.-Col. R. H. Lee, I.M.S.ret. (4th donation).
 £5 5s.—Dr. J. M. Alston, London; Dr. J. Walker Brash, London; Dr. T. J. Cronin, Birmingham (3rd donation); Dr. J. K. Donald, London; Dr. C. Gibson, Worthing (2nd donation); Sir William Hale-White, Oxford; Dr. W. E. Hayes, Potters Bar; Major W. Happer, I.M.S. (23th donation); Miss K. McArthur, Harrow (3rd donation); Dr. J. A. Moody, Ilford; Capt. H. B. Morris, R.A.M.C.; Dr. D. S. Poole, Teddington (2nd donation); Dr. John F. Seales, Mountain Ash; Dr. A. C. Shuttleworth, Chester; Dr. V. D. C. Wakeford, London (2nd donation); Dr. G. C. L. Woodroffe, Hampton (2nd donation).
 £5.—Major S. Bradshaw, R.A.M.C.; Dr. N. F. Coghill, London (4th donation); Dr. J. H. Crofton, Ware (3rd donation); Major F. R. Glover, R.A.M.C.; Surg. Lieut. N. S. Hepburn, R.N.; Drs. H. and E. Johnson, London; Dr. R. Shove, Cullompton (2nd donation).
 £3 3s.—Anonymous; Mr. F. C. Dwyer, Liverpool; Dr. D. Kinsella, Stonehouse; Dr. G. Neely, London.
 £2 2s.—Dr. W. T. Beswick, London (2nd donation); Lieut.-Col. N. Bickford (19th donation); Dr. C. W. Elson, Worthing; Dr. Julian T. E. Evans, West Worthing; Dr. T. B. Evans, Prestatyn (29th donation); Dr. J. I. Lyons, Heston; Dr. A. G. McArthur, London (4th donation).
 £2.—Capt. S. Citron, R.A.M.C.; Dr. H. Stalker, Edinburgh (2nd donation).
 £1 10s.—Dr. E. G. Wilson, Sheffield.
 £1 1s.—Mrs. R. J. Buxton, Wriarton; Dr. F. R. Corfe, Petersfield (2nd donation); Dr. R. Lynn, Bath; Miss C. M. Outley, Hove; Dr. R. E. M. Taunton, London (2nd donation).
 £1.—Dr. Anna P. Martin, Naapur.
 11s.—Dr. J. Slaggett, Delabole.
 £229 2s.—Practitioners in Birmingham Central B.M.A. Division—per Dr. F. E. Gould (amount already sent £393 3s.); Dr. D. Priestley Smith £21 (3rd donation); Dr. Mabel E. Prosser £3 3s. (2nd donation); Dr. H. Featherstone £2 2s.; Dr. J. Griffin £5 3s. (2nd donation); Dr. T. L. Hardy £10 10s. (3rd donation); Dr. J. L. Brown £2 2s. (3rd donation); Dr. G. J. Allan £1 1s.; Dr. A. M. Cunn £4 4s.; Anonymous £10s.; Dr. Frances Braid £5 5s. (2nd donation); Dr. J. P. Good £5 5s. (2nd donation); Dr. Jean L. Hallam £2 2s.; Dr. A. J. Davies £3 3s.; Dr. W. Summers £3 3s. (2nd donation); Dr. J. S. M. Connell £21; Dr. G. Webb £5 5s.; Dr. A. Brian Taylor £10 10s. (2nd donation); Dr. H. W. Donovan £15 (3rd donation); Dr. F. Selby Tait £2 2s.; Dr. J. Radner £2 (2nd donation).

£225 8s. 6d.—Practitioners in Derby Division—per Dr. E. C. Dawson (amount already sent £208 0s. 7d.): Drs. Denny, Highfield, and Isaac £15 15s. (2nd donation); Anonymous £10 10s.; Mr. C. H. Bamford £10 10s.; Dr. J. Adam £5 5s.; Drs. H. C. and M. C. Bell £5 5s. (2nd donation); Drs. Broster and Fletcher £5 5s. (2nd donation); Dr. T. D. Donegan £5 5s.; Mr. M. L. Edwards £5 5s.; Dr. A. R. Elsom £5 5s. (2nd donation); Dr. G. E. Kidman £5 5s. (2nd donation); Dr. F. G. Lischer £5 5s.; Dr. J. B. Mitton £5 5s. (2nd donation); Dr. E. U. H. Pentreath £5 5s.; Mr. J. R. Ratcliffe £5 5s. (2nd donation); Dr. Kathleen Riddle £5 5s. (2nd donation); Mr. W. G. Rose £5 5s. (2nd donation); Dr. C. Rudge £5 5s.; Dr. R. P. Bliss £5 5s. (2nd donation); Dr. W. E. Haigh £5 5s. (2nd donation); Dr. T. J. Kirkpatrick £5 5s. (3rd donation); Dr. T. Tully £5 5s.; Dr. A. Burns £3 3s. (2nd donation); Dr. E. C. Dawson £3 3s. (4th donation); Dr. W. Paterson Shand £3 3s.; Dr. J. D. Crerar £2 12s. 6d.; Dr. H. Barber £2 2s. (2nd donation); Dr. R. Blair £2 2s. (2nd donation); Dr. R. L. Brown £2 2s. (2nd donation); Dr. R. Gordon Cooke £2 2s. (2nd donation); Dr. E. Crawley £2 2s.; Dr. W. M. Dinwoodie £2 2s.; Dr. M. H. Elmitt £2 2s. (3rd donation); Mr. R. L. Flett £2 2s.; Dr. T. Futers £2 2s.; Dr. E. J. Goldman £2 2s.; Dr. J. R. Hollick £2 2s. (3rd donation); Dr. G. F. Keatinge £2 2s.; Mr. C. D. Lochrane £2 2s. (3rd donation); Dr. A. M. MacCormick £2 2s. (2nd donation); Dr. E. M. MacDonald £2 2s. (2nd donation); Dr. D. Macfarlane £2 2s. (2nd donation); Dr. J. C. Macfarlane £2 2s. (2nd donation); Dr. A. R. McKail £2 2s. (2nd donation); Dr. J. B. S. Morgan £2 2s.; Dr. T. B. Nicholas £2 2s.; Dr. C. Penny £2 2s.; Dr. H. C. Robertson £2 2s. (2nd donation); Dr. J. Murray Robertson £2 2s. (2nd donation); Dr. C. G. Shcrown £2 2s.; Dr. J. W. Smith £2 2s.; Dr. F. Starritt £2 2s.; Dr. G. W. R. Thomson £2 2s. (4th donation); Dr. L. O. Watt £2 2s. (2nd donation); Dr. H. F. Blood £2 3s. (3rd donation); Drs. Lindsey and Hodson £2 2s.; Dr. E. L. R. Norton £2 2s. (2nd donation); Dr. J. L. Anderson £1 1s. (2nd donation); Dr. J. W. Barber £1 1s.; Dr. C. W. J. Brasher £1 1s.; Dr. R. B. Dobson £1 1s.; Dr. G. S. Dow £1 1s.; Dr. Gordon Gillies £1 1s. (2nd donation); Dr. E. J. Goldsmith £1 1s.; Dr. E. H. B. Grey £1 1s. (2nd donation); Dr. J. M. M. Heap £1 1s.; Dr. G. W. Iliffe £1 1s. (2nd donation); Dr. Q. Madge £1 1s. (3rd donation); Dr. J. Palmer £1 1s.; Dr. A. M. Ramsay £1 1s. (2nd donation); Dr. W. R. Soutter £1 1s.; Dr. A. J. Wilson £1 1s.; Dr. V. J. Woodward £1 1s. (2nd donation); Dr. W. H. Williams £1 1s.; Dr. F. Houston 10s.

£213 5s.—Practitioners in Bournemouth B.M.A. Division—per Dr. N. Ross Smith (amount already sent £520 7s. 5d.): Dr. F. C. Bottomley £10 10s. (3rd donation); Dr. W. McNaughton £10 10s. (2nd donation); Mr. N. Ross Smith £10 10s. (3rd donation); Dr. E. C. Parker Williams £10 10s. (3rd donation); Mr. S. G. Luker £10 10s. (3rd donation); Dr. A. M. Barron £5 5s. (2nd donation); Dr. A. Leslie Blunt £5 5s.; Dr. C. P. Charles £5 5s. (3rd donation); Dr. C. Colmer Davies £5 5s. (2nd donation); Dr. David Hardie £5 5s. (2nd donation); Dr. F. Heasman £5 5s. (2nd donation); Dr. R. M. B. Owens £5 5s. (2nd donation); Dr. Newton Matthews £5 5s. (2nd donation); Dr. P. J. Montgomery £5 5s. (3rd donation); Mr. Campbell Shaw £5 5s. (3rd donation); Dr. G. S. Small £5 5s.; Dr. C. W. Branson £5 5s. (2nd donation); Dr. A. R. Paterson £5 5s. (2nd donation); Surg. Capt. A. T. Rivers £5 5s.; Dr. E. Croft Watts £5 5s. (2nd donation); Dr. S. Devine £3 3s. (3rd donation); Dr. J. Dixon Green £3 3s. (2nd donation); Dr. J. L. Reeve £3 3s. (3rd donation); Dr. R. Risk £3 3s. (2nd donation); Dr. J. Sharp £3 3s. (4th donation); Col. H. S. Anderson £2 2s. (2nd donation); Dr. F. Barker £2 2s. (2nd donation); Dr. G. Chesney £2 2s.; Dr. I. Duguid £2 2s. (2nd donation); Dr. R. Vaughan Facey £2 2s.; Dr. E. Johnson £2 2s.; Dr. A. S. Mackie £2 2s. (2nd donation); Dr. Doris Odium £2 2s. (3rd donation); Dr. D. W. R. Pratt £2 2s.; Dr. J. W. Redgate £2 2s.; Dr. B. Hall Reid £2 2s. (2nd donation); Dr. G. S. A. Scott £2 2s.; Major P. A. Stewart £2 2s. (2nd donation); Dr. F. D. Walker £2 2s.; Dr. G. H. S. Daniell £2 2s.; Col. P. MacKessack £2 2s. (4th donation); Dr. A. Mackenzie Ross £2 2s. (2nd donation); Dr. C. B. Mooring Aldridge £1 10s. (2nd donation); Dr. C. T. Hawkins £1 10s. (2nd donation); Dr. D. Basker £1 1s.; Dr. T. M. Bell £1 1s. (3rd donation); Dr. W. Moss Bristowe £1 1s.; Dr. M. Bentley £1 1s.; Dr. E. S. Bowes £1 1s. (3rd donation); Dr. K. B. Clarke £1 1s. (2nd donation); Dr. P. C. Cumber £1 1s. (2nd donation); Dr. A. L. Dobbryn £1 1s. (2nd donation); Dr. H. Granger £1 1s.; Dr. J. G. McKay Grant £1 1s. (2nd donation); Dr. S. W. Green £1 1s. (2nd donation); Dr. A. W. Hall £1 1s. (2nd donation); Dr. A. W. Howarth £1 1s.; Dr. J. R. Hunter £1 1s.; Dr. J. R. John £1 1s.; Dr. Doris G. Litherland £1 1s. (2nd donation); Dr. R. Macdonald £1 1s.; Dr. H. V. Mitchell £1 1s. (2nd donation); Dr. M. S. Mitchell £1 1s. (2nd donation); Dr. James Nicholson £1 1s. (2nd donation); Dr. C. E. R. Norman £1 1s.; Dr. B. Roditi £1 1s.; Dr. C. J. Royston £1 1s. (2nd donation); Dr. C. J. Sandford £1 1s. (2nd donation); Dr. R. A. Scott £1 1s.; Dr. J. Sharp £1 1s. (3rd donation); Dr. A. F. Shepherd £1 1s.; Dr. C. P. Woodstock £1 1s.

£171 2s.—Practitioners in Willesden B.M.A. Division—per Dr. W. Paterson (amount already sent £36 10s.): Dr. Mabel Brewster £10 10s.; Dr. H. Brostoff £10 10s.; Dr. G. F. Buchan £10 10s.; Dr. H. A. Faulkner £10 10s.; Dr. W. L. Gillbard £10 10s.; Dr. J. A. Gordon £10 10s.; Dr. V. James £10 10s.; Dr. C. de B. Thomson £8 8s.; Dr. M. A. M. Bigby £6 6s.; Dr. Grace Anderson £5 5s.; Dr. F. P. Bennett £5 5s.; Dr. W. Donoghue £5 5s.; Dr. L. Phillips £5 5s.; Dr. A. L. Rozelaar £5 5s.; Dr. P. D. Scott £5 5s.; Dr. H. M. Setna £5 5s.; Dr. K. C. S. Skene £5 5s.; Dr. S. Stockman £5 5s.; Dr. J. M. £132 11s.—Practitioners in Nottingham B.M.A. Branch—per Dr. A. D. Frazier.

£120 13s. 6d.—Practitioners in Sheffield B.M.A. Division—per Dr. T. Lodge (amount already sent £295 3s. 7d.): Dr. M. L. McKinnon £5 5s.; Dr. K. Mackenzie £5 5s. (2nd donation); Dr. A. E. Naish £5 5s. (2nd donation); Dr. B. L. Droller £1 1s.; Dr. H. Brown £2 2s. (2nd donation); Dr. J. H. Wilbourn £5 5s. (2nd donation); Dr. G. E. Tisley £10 10s.; Dr. E. K. Abbott £2 2s.; Sir A. J. Hall £5 5s.; Dr. F. T. Thorpe £2 2s.; Dr. M. M. Owen £1 1s. 6d.; Dr. H. R. Vickers £5 5s.; Dr. D. C. Barron £4 4s. (3rd donation); Mr. J. B. F. Wilson £5 5s. (2nd donation); Dr. W. T. Buchan £5 5s.; Dr. A. Hart £3 3s.; Dr. H. M. Cohen £1 1s. (2nd donation); Dr. P. E. Sylvester £2 2s.; Dr. J. Jordan Coleman £2 2s. (2nd donation); Dr. H. Midgley Turner £2 2s. (2nd donation); Dr. W. Vincent £5 5s. (2nd donation); Dr. C. S. O'Flynn £3 3s. (2nd donation); Dr. Agnes S. Nutt £1 1s. (2nd donation); Dr. A. G. H. Mackintosh £2 2s.; Dr. R. D. Downie £5 5s.; Dr. J. G. Heathcote £1 1s.; Dr. M. R. Powell £5 5s.; Dr. Ethel W. Morris £2 2s. (2nd donation); Dr. W. F. O'Connell £5 5s.; Mr. L. B. Patrick £3 3s.; Dr. M. Rushbrooke £5 5s. (5th donation); Dr. J. Wier £1 1s.; Dr. J. L. A. Grant £5 5s.

£101 18s.—Practitioners in Lancaster B.M.A. Division—per Dr. W. George (amount already sent £396 9s.): Mr. E. Holmes £21 1s.; Dr. and Mrs. John Wilkie £21 1s. (5th donation); Dr. G. M. Kay £10 10s. (2nd donation); Dr. J. D. Silverston £10 10s. (3rd donation); Dr. L. Mather £10 10s. (3rd donation); Dr. C. J. Henderson £5 5s. (3rd donation); Drs. E. B. and T. L. Dowell £5 5s. (3rd donation); Dr. J. A. Tomb £5 5s. (3rd donation); Dr. P. S. Byrne £3 3s.; Dr. C. Alston Hughes £3 3s.; Dr. W. P. Stocks £3 3s.; Dr. T. Taylor £2 2s.; Dr. E. M. Goodall £1 1s.; Dr. W. F. Lyle £1 1s. (2nd donation).

£100.—Practitioners in Dumfries and Galloway B.M.A. Division—per Dr. J. G. McWhirter; Practitioners in Oxfordshire B.M.A. Division—per Dr. C. J. L. Wells.

£88 17s. 6d.—Practitioners in Newcastle-upon-Tyne B.M.A. Division—per Mr. Weldon Watts (amount already sent £475 0s. 6d.): Dr. D. Ramage £10 10s.; Mr. J. Gilmour £5 5s. (2nd donation); Dr. H. J. Nicholson £1 1s. (2nd donation); Mr. W. A. Hewitson £2 2s. (3rd donation); Dr. S. M. Garston £2 2s. (2nd donation); Dr. C. Neubauer 10s.; Mr. J. S. Arkle £10 10s. (3rd donation); Dr. Mary C. Livingstone £3 3s. (2nd donation); Mr. H. P. Bennett £5 5s. (2nd donation); Dr. S. Whately Davidson £10 10s. (3rd donation); Dr. G. Davison £3 3s. (3rd donation); Dr. J. A. Brand £2 2s. (2nd donation); Dr. M. F. Thomas £1 1s.; Dr. T. H. Bates £2 2s. (2nd donation); Dr. Enid L. Hughes £1 1s. 6d. (3rd donation); Dr. W. Stewart Smith £1 1s.; Mr. Norman Hodgson £10 10s. (2nd donation); Dr. E. D. Smith £2 2s. (2nd donation); Prof. F. J. Nattrass £2 2s.; Mr. Weldon Watts £5 5s. (2nd donation); Dr. J. E. Basham £2 2s. (2nd donation); Prof. R. P. Ranken Lyle £5 5s.

£88 7s.—Practitioners in Scunthorpe B.M.A. Division—per Dr. J. R. Baker (amount already sent £68 4s. 6d.).

£86 12s. 6d.—Practitioners in Bromley B.M.A. Division—per Dr. M. Prout.

£78 4s. 6d.—Practitioners in Lincoln B.M.A. Division—per Dr. C. A. Bagot Walters (amount already sent £536 10s.).

£72 13s.—Practitioners in Hampstead B.M.A. Division—per Mr. S. Boyd (amount already sent £43 15s.).

£59 14s.—Practitioners in the Croydon B.M.A. Division—per Dr. A. S. Forbes (amount already sent £209 17s. 6d.): Dr. T. Murphy £5 5s. (2nd donation); Dr. G. E. E. Bryane Nicholls £5 5s.; Dr. Olive G. Potter £5 5s.; Dr. Eileen M. Saxton £5 5s. (4th donation); Dr. C. Corben £5 5s. (2nd donation); Dr. E. R. Stone £5 5s.; Dr. A. S. Niven £3 3s.; Dr. F. G. Pailthorpe £3 3s.; Dr. A. Rose £3 3s. (2nd donation); Dr. D. G. A. Stewart £3 3s.; Dr. J. Appleyard £2 2s. (2nd donation); Dr. M. C. Breese £2 2s.; Dr. W. H. Hardy £2 2s. (3rd donation); Dr. H. Ross £2 2s.; Dr. C. F. Swinton £2 2s.

C. A. Posford £1 10s.; Dr. E. R. Edbrooke £1 1s.; Dr. T. S. cDevitt £1 1s.; Mrs. S. B. Jackson Smith £1 1s.; Dr. J. A. H. kes £1 1s.

£59 7s.—Practitioners in Blackburn B.M.A. Division—per Dr. Driscoll (amount already sent £76 9s.); Dr. J. S. Cooper £10 nd donation); Dr. J. K. Cumming £5 5s.; Dr. F. W. Taylor 5s.; Drs. A. and J. B. Leigh £4 4s. (2nd donation); Dr. N. M. reeves £3 3s.; Dr. J. McDonald £3 3s. (2nd donation); Dr. D. Driscoll £3 3s. (2nd donation); Dr. A. H. Gregson £2 2s.; Dr. Hawke-Genn £2 2s.; Dr. J. Jennings £2 2s.; Dr. J. Kyle 2s. (2nd donation); Dr. A. C. Newman £2 2s.; Mr. C. M. Pearce 2s. (2nd donation); Dr. R. Pendlebury £2 2s. (2nd donation); r. P. N. Rampal £2 2s. (2nd donation); Dr. J. Ross £2 2s.; Dr. James Scott £2 2s.; Dr. H. Southworth £2 2s.; Dr. R. C. U. arrington £2 2s. (2nd donation); Dr. T. S. Hall £2 2s.; Dr. C. utherland £2 2s.

£57 13s.—Practitioners in City of Aberdeen B.M.A. Division—per r. H. Fowle (amount already sent £149 15s.).

£56 5s.—Practitioners in Marylebone B.M.A. Division—per Mr. ric Steeler (amount already sent £391 17s.); Dr. J. B. Mackenzie 10; Sir Maurice Cassidy £5 5s. (3rd donation); Dr. J. D. Hindley- mith £5; Mr. F. L. W. Capps £5 5s.; Mr. Humphrey Neame £5; r. Geoffrey Evans £10 10s.; Mr. Frank W. Law £5; Dr. P. rescu £5 5s.; Dr. Amy Thoms £5 (2nd donation).

£81 19s.—Insurance Practitioners in London—per Dr. F. Gray, ondon Panel Committee (amount already sent £157 4s.); Dr. M. fClean £2 2s.; Dr. A. B. Wingate £1 1s. (2nd donation); Dr. anley Brass £2 2s. (2nd donation); Dr. Norah E. Trouton £5; r. F. Joyce £3 3s.; Drs. Kathleen H. Matthews and Elizabeth J. arper £2 2s.; Dr. F. H. Robbins £10 10s.; Dr. N. B. Farman 6 6s.; Dr. P. V. Dillon £5; Dr. D. Haydon Jones £3 3s.; Dr. W. J. udahy £2 2s. (2nd donation); Dr. O. E. Manasse £2 2s.; Dr. E. R. weaney £2 2s. (2nd donation); Dr. L. W. Batten £1 1s. (3rd dona- on); Dr. E. M. Herbert £1 1s.; Dr. J. G. Lahiff £1 1s.; Dr. M. elvin £1 1s.; Dr. M. Ripka £1 1s.; Dr. A. F. Whyte £2 2s.; Dr. . H. Porter £5; Dr. L. Shear £5 5s.; Dr. H. H. Sanguinetti £2 2s.; r. D. S. Stewart £10 10s.; Dr. H. K. Banda £5.

£51 10s.—Practitioners in Wakefield, Pontefract, and Castleford B.M.A. Division—per Dr. N. Stuart Twist (amount already sent £70 3s.); Dr. J. D. Bottomley £5 5s. (3rd donation); Dr. D. Downie 5 5s. (3rd donation); Dr. A. Hird £5 5s. (2nd donation); Dr. D. H. ussell £5 5s. (2nd donation); Dr. R. B. Radcliffe £5 (3rd dona- on); Dr. H. Scholefield £5 (3rd donation); Dr. N. S. Twist £5 4th donation); Drs. Walker and Heron £5; Dr. J. J. Reynolds 3 3s. (3rd donation); Dr. T. G. Clarke £2 2s. (2nd donation); r. H. L. N. £5 5s.

£47 17s. 6d.—Practitioners in Isle of Man B.M.A. Branch—per r. C. G. Pantin (amount already sent £189 4s.).

£42 19s. 8d.—Practitioners in Dumbartonshire B.M.A. Division amount already sent £74 1s. 7d.); Dr. G. Swanson £1; Dr. W. ibson £3 3s. (2nd donation); Dr. M. Purvis £3 3s.; Dr. Jessie W. gillvie £2 2s.; Dr. Wm. Anderson £1 1s.; Dr. John S. Clark £5; r. A. D. Downes £2 2s.; Dr. J. W. Cook £5; Insurance practi- oners £20 8s. 8d.

£42 15s.—Practitioners in Mid Essex B.M.A. Division—per Dr. . T. Whitley (amount already sent £117 14s. 6d.).

£38 16s.—Practitioners in Buckinghamshire B.M.A. Division—per r. R. W. McConnel (amount already sent £599 6s. 6d.).

£34 6s.—Practitioners in North Bedfordshire B.M.A. Division— per Dr. J. C. Boyde: Mr. G. J. Griffiths £2 2s.; Dr. D. H. Irish 2 2s.; Dr. W. A. Barnes £5 5s. (2nd donation); Dr. L. G. M. Pago £5; Miss M. Moore White £5; Dr. J. L. Maxwell £1 1s.; Dr. R. W. R. van Langenberg £1 1s.; Dr. Sarah Roberts £5 5s.; Dr. R. Stuart £2 10s.; J. C. B. £5.

£33 17s.—Practitioners in Stratford B.M.A. Division—per Dr. H. C. Boyde (amount already sent £99 4s.); Dr. A. V. S. Davies £5 5s.; Drs. Rosc. Bannor, and Smitber £10 10s.; Collection at Division meeting £18 2s.

£33 12s.—Practitioners in Bolton B.M.A. Division—per Dr. D. P. Simpson (amount already sent £75 3s.); Dr. D. McGhee £5 5s.; Dr. S. F. Berndt £5 5s.; Dr. J. Fletcher Smith £3 3s.; Drs. M. E. and E. P. Johnson £3 3s.; Dr. R. D. Mothersole £2 2s. (2nd dona- on); Dr. H. Leslie £2 2s.; Dr. G. D. McKenzie £2 2s. (2nd dona- on); Dr. H. P. Goldman £2 2s. (2nd donation); Dr. J. A. Smith £2 2s. (2nd donation); Dr. F. Vance £2 2s.; Dr. D. P. Simpson £2 2s.; Dr. A. L. Climcr £1 1s. (2nd donation); Dr. J. R. Monks £1 1s.

£27 1s.—Practitioners in Westmorland B.M.A. Division—per Dr. Elizabeth M. Kemp (amount already sent £39); Dr. G. H. Edge- combe £5 5s. (2nd donation); Dr. W. B. Cockill £5 (2nd donation); Drs. Craig and Holmes £4 4s.; Dr. O. B. Buckley £2 2s. (4th dona- on); Dr. A. Matchett £2 2s. (2nd donation); Dr. R. G. Mathews £2 2s. (2nd donation); Dr. J. H. Patterson £2 2s.; Dr. Frances Taylor £2 2s.; Dr. A. Wight £2 2s.

£26 5s.—Practitioners in Wigan B.M.A. Division—per Dr. G. A. Talwrn-Jones.

£23 2s.—Members of W. Suffolk Division not contributing through Panel Committee—per Dr. B. E. A. Batt.

£22 17s.—Members of Greenwich and Deptford B.M.A. Division —per Dr. W. Smith (amount already sent £32 18s.); Dr. T. D. Sayers £10 10s.; Dr. W. Smith £5 5s. (2nd donation); Dr. W. B. Silas £5 (2nd donation); Dr. J. Loftus £2 2s. (2nd donation).

£11 6s.—Practitioners in Plymouth B.M.A. Division—per Dr. Mabel Ramsay (amount already sent £415 15s. 6d.); Dr. Marjorie V. B. Hlopkins £2 2s.; Dr. J. Smalley £5 (2nd donation); Dr. John Walsh £2 2s.; Dr. D. O. Twining £2 2s.

£10 5s.—Practitioners in Tyneside B.M.A. Division—per Dr. D. Ross.

£9 9s.—Practitioners in East Herts B.M.A. Division—per Dr. J. S. Ross (amount already sent £371 13s. 1d.).

£8 3s.—Practitioners in Furness B.M.A. Division—per Dr. Lorton Wilson (amount already sent £74 19s. 6d.); Sir Matthew Fell £5 (2nd donation); Dr. L. Wilson £3 3s. (3rd donation).

£7 7s.—Practitioners in Stirling B.M.A. Branch—per Dr. W. L. Cuthbert (amount already sent £128); Dr. D. Younie £1 1s.; Dr. M. Harper £3 3s.; Dr. R. T. Campbell £3 3s.

£4 4s.—Practitioners in Camberwell B.M.A. Division—per Dr. A. S. Hatch: Drs. Hatch and Hunnard £2 2s. (2nd donation); Dr. T. Richardson £2 2s.

£3.—Practitioners in Leigh B.M.A. Division—per Dr. J. H. Young (amount already sent £82 13s.); Dr. H. Tickle (3rd donation).

£2 2s.—Practitioners in Tunbridge Wells B.M.A. Division—per Dr. A. M. Pollock (amount already sent £48 19s.); Dr. K. D. Marriner.

£1 1s.—Practitioners in Matabeleland B.M.A. Branch (amount already sent £73 12s. 3d.).

£25.—Honorary Medical Staff of the General Hospital, Stratford-on-Avon (amount already sent £124).

£500.—Those doctors who worked the Unaccompanied Evacuee Children's Fund in Cornwall.

£36.—Members of the Eastern Valley Medical Association, Garndiffaith, Mon.—per Dr. E. J. Williams.

Local Medical and Panel Committees

£500.—Durham (2nd donation); Lancashire (2nd donation).

£200.—Sheffield (2nd donation).

£150.—Bedfordshire (3rd donation); Somerset (4th donation).

£135 17s.—Hampshire (2nd donation).

£112 7s.—East Riding of Yorkshire (2nd donation).

£105.—Croydon (2nd donation).

£100.—Northumberland (2nd donation); Nottinghamshire (2nd donation); County of Salop (2nd donation).

£65 17s. 6d.—Worcester City (2nd donation).

£57 15s.—Gloucestershire (3rd donation).

£54 2s.—Newcastle-upon-Tyne (19th donation).

£51 18s. 1d.—Soke of Peterborough.

£50.—Derby; York (2nd donation).

£42 5s. 8d.—County of Ayr (21st donation).

£31 15s. 7d.—Barnsley (4th donation).

£21.—Huntingdonshire (3rd donation).

£20.—Banffshire.

£18 13s. 7d.—East Lothian (20th donation).

£15.—West Bromwich.

£2 2s.—East Ham (2nd donation).

£1 1s.—Cheshire.

Cheques, payable to the Medical War Relief Fund, should be sent to the Hon. Treasurer of the Fund, British Medical Association House, Tavistock Square, London, W.C.1.

Correspondence

Release from the R.A.F.

STR.—I must apologize for adding to the long list of letters on this subject, but one day it will dawn on those responsible for recruitment and distribution of Service medical officers that we cannot all be out of step. Others have related the facts with regard to unequal release of medical officers in the three Services. This is designed to show at least one reason why the R.A.F. is so sadly behind. During the last three months at this station, the average sick seen daily has been 1.33. I am now told I must proceed to another unit, where there are a quarter the number of potential patients. It is reasonable to anticipate that the average daily sick will "total" 0.33 or, to make it appear even worse, one airman reporting sick every third day. No longer can the claim be made that there must be an M.O. on a station where aircraft land, as in this area the number of stations without an M.O. will, in a matter of days, exceed those with one. What justification can there be for an M.O. on either of these stations mentioned? In both cases the R.A.M.C. officers are willing to deal with the microscopic amount of sickness, and they are comparatively near.

Is there no authority, no person, no committee who can do something about this chaotic state of affairs, and put a stop to this blatant misuse and waste of medical manpower? Cannot Mr. Bevan find just one more committee to investigate the waste of doctors in the Service at present? I admit it would cause grave repercussions in some circles. I have no

complaint at my "Post-war Pension" but I eagerly await just half a day's work. Like the athlete I should like to get into training and gradually increase the pace, so that I can fit myself for the full-time occupation, in civil life, when once again I can enjoy my work.—I am, etc.,

"R.A.F. UNEMPLOYED."

Demobilized Doctors as Assistants

SIR,—I was interested in the correspondence about assistants, and also in arrangements for the settlement of returning Service doctors. A friend of mine applied for and got an assistant-ship last January, after leaving the Army. There was to be a trial period of six months. At the end of this period the principal announced that he could no longer afford an assistant. He made no suggestion that my friend was unsuitable. Now he had got an assistant for the worst period, and also a holiday for himself for three weeks without having to pay a locum. I would be glad if you would publish this letter as a warning to other Service doctors who might be caught the same way. I would also like to comment on the remark by Dr. Vaughan Jones that practices were available for returned Service men at reduced premiums. I have not found it so. If Dr. Vaughan Jones reads the advertisements in the *Journal* he will see for himself the colossal premiums asked for doctor's houses. I feel strongly that the returned Service doctor should get more consideration. I am sure that the medical profession as a whole would wish it so, but this cannot be done by misleading statements.—I am, etc.,

EX-SERVICE ASSISTANT.

Association Notices

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1947. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1947, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946.

Diary of Central Meetings

JULY

23. Tues. Council, 10 a.m.
Annual Representative Meeting, 2 p.m. (and succeeding days).
24. Wed. Annual General Meeting, 12.30 p.m. (The first meeting of the new Council will be held at the close of the A.R.M.)

Branch and Division Meetings to be Held

SOUTHAMPTON DIVISION.—At Royal South Hants and Southampton Hospital, Southampton, Wednesday, July 17, 8.30 p.m. Annual general meeting.

Meetings of Branches and Divisions

MONMOUTHSHIRE DIVISION

Lady Florey gave a B.M.A. Lecture on penicillin to a meeting of the Monmouthshire Division on May 16, Dr. G. R. Strong presiding. She began by saying that there were a very large number of publications on penicillin—on the treatment of gonorrhoea there were some 900 alone—but even so, the fundamental properties of the drug as given in the earliest publications had not been contradicted. Penicillin did little harm to the human being and caused no toxic symptoms. Any dose could be given; there was a basic dose for infection, but over and above that it did not really matter

what was given. It could be destroyed by heat, by acid (which was why it was not given by the mouth), and by oxidizing agents. It could not be used in combination with chlorides, as they neutralized its effect. It was itself destroyed by bacteria, which could be combated by keeping it protected from the air. Preparations used for local administration were kept covered and then changed once a week; creams or solutions ran the risk of deterioration; powders contained a sulphonamide and were kept in a refrigerator. Success with penicillin depended on access being obtained to the part to be treated. By giving it intramuscularly every part of the body could be reached via the circulatory system—e.g., a retained placenta or a blood clot. This might stop some of the infection, but it would not get into the placenta and the condition was liable to flare up. If penicillin was applied locally, as in impetigo, the root of the infection would not be reached, only the scab. The dose for systemic treatment, irrespective of how it was introduced, was 120,000 units in 24 hours. If given intramuscularly it should be divided into 8 doses of 15,000 units every 3 hours. For a breast abscess 60,000 units should be given twice a day. A pleural effusion should be aspirated and an injection of 240,000 units given every two days. A dose of 500 units per gramme would produce a much higher concentration on the surface if given locally than if given intramuscularly. The intramuscular method of administration came into force after D-day, when larger supplies of the drug were available; instillation, which had to be carried out in an operating theatre, was then almost forgotten. Insufflation might dry the wound, and if the skin surface was infected a crust would be formed and the infection kept below it. It was, however, extremely useful in a small surface wound, but should not be used for a sinus. In cases of pneumonia or osteomyelitis we had been using drugs which were antipyretic—sulphonamides—and the temperature was brought down, but the infection was not necessarily controlled. With penicillin the temperature came down slightly after a week; but it was better to watch the patient than to watch the temperature, because even though pyrexia remained the infection was improving.

The lecture, which was well attended, was very much appreciated and many questions were asked. A vote of thanks was proposed by Dr. Grahame Jones and seconded by Dr. Hastings and carried with acclamation.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tues., 5.30 p.m. Ballot for election to the Fellowship.

Section of Proctology.—Wed., 5.30 p.m. Annual general meeting: Election of Officers and Council. Discussion: Some Peculiarities in the Surgical Pathology of Malignant Disease of the Ano-rectal Region. Opener: Dr. Cuthbert Dukes, followed by Mr. Kenneth James: Surgical Complications of Amoebic Dysentery.

BIOCHEMICAL SOCIETY.—At Department of Biochemistry, University New Buildings, Teviot Place, Edinburgh, Fri., 10.30 a.m. Communications and demonstrations.

MACKENZIE INDUSTRIAL HEALTH LECTURE.—At B.M.A. House, Tavistock Square, W.C., Wed., 5.45 p.m. Dr. Donald Hunter: Academic Aspects of Industrial Medicine.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tues., 5 p.m. The Bertram Louis Abrahams Lecture by Prof. C. A. Lovatt Evans, F.R.S.: The Outlook of Physiology To-day.

APPOINTMENTS

TREISSMAN, H., F.R.C.S., D.O.M.S., Honorary Ophthalmic Surgeon. King Edward Memorial Hospital, Ealing.

WINCHESTER: ROYAL HAMPSHIRE COUNTY HOSPITAL.—Honorary Assistant Surgeons: J. Rubin, F.R.C.S.Ed., P. W. Ingram, F.R.C.S.Ed. Honorary Medical Officer in Charge of X-ray Department: R. I. Roberts, M.R.C.S. L.R.C.P., D.M.R. Honorary Orthopaedic and Traumatic Surgeon: G. N. Golden, F.R.C.S. Honorary Psychiatrist: W. L. Neustatter, M.D. Honorary Assistant Ear, Nose, and Throat Surgeon: G. S. Midgley, M.R.C.S., D.L.O.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BURFIELD.—On June 26, 1946, at Kampala, Uganda, to Phemie (née Child) wife of Dr. G. A. Burfield, Colonial Medical Service, Bukoba, Tanganyika Territory, a daughter.

STALEY.—On July 2, 1946, at the Osborn Nursing Home, Thetford, to Bill (née Williams), wife of Dr. G. R. Staley, M.B., B.S., a daughter—Anne.

DEATHS

ADAMS.—On June 27, 1946, very suddenly, Dorothy Mann Adams, M.B. B.Ch., late R.A.F.V.R., greatly beloved sister of Ursula Price, St Leonards House, Seaford, Sussex.

LOUGHLIN.—On May 27, 1946, suddenly, at his home, Becton Corner, Barton-on-Sea, Dermot Loughlin, D.Sc., M.B., B.S.Lond., late of Saxonhurst Woolston, aged 60.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. Christopher Hardwick at Nuffield House, Guy's Hospital, S.E.1.; Mr. P. H. Newman, F.R.C.S., at 66, Harley Street, W.1. (Langham 3808).

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 20 1946

TOTAL WAR ON CANCER*

BY

G. F. STEBBING, M.B., B.S., F.R.C.S., F.F.R.

Hon. Secretary, Radium Commission

hat we have to make war on cancer is no new idea. indeed, the British Empire Cancer Campaign in its title makes use of a military term, for the first meanings of "campaign" in the Oxford English Dictionary are: A series of military operations in a definite theatre with one objective; organized course of action.

Up to the beginning of the war of 1914-18 the idea in most people's minds was that war was a business for the fighting forces of the opposing countries, and it was a rude shock for many of us to find that the line between the fighting forces and the civilians was not very clearly defined, and that before the conflict was ended a large number of civilians had had to play an important part in the effort for victory. The war that has recently ended has made it clear to everybody, in every nation, that hostilities are no longer the concern only of the military forces but that every man, woman, and child of each side is exposed to the dangers of the fighting and must play a full part in the complex activities necessary to enable victory to be achieved.

An Insidious Foe

When our Campaign was started it was realized that our foe, cancer, was an insidious and mysterious foe, and that if we were to overcome it we should have to organize a series of operations on a wide scale in a definite field and with the objectives of discovering the cause of and finding a cure for cancer. It was envisaged that the soldiers who would do the fighting were the scientists in the laboratories and the doctors in the consulting-rooms and operating theatres, and that to keep them at work under the best conditions they must be helped by an organization that would provide laboratories and hospitals with whatever funds were necessary to carry on the war. It was a campaign such as we were familiar with in the military sense in those days, and some notable victories were won. Some of the causes of cancer have been ascertained, and some methods of treatment of great value have been evolved: these represent battles that have been won; but the war goes on, and we are still a long way from victory.

The Registrar-General states that 600,000 people died in England and Wales during 1944, that 71,814 of these were certified as having died of cancer, and he tells us that cancer is the second commonest cause of death. There is a very important thing to note about this figure: since the Registrar-General began to analyse the causes of death the number of deaths attributed to cancer increased slowly but surely every year until 1944, and in that year, for the first time, the number was smaller than in the year before—smaller by 226. Many factors have to be taken into consideration, but there is reason to hope that this may mean the turning of the tide, and that a small beginning has been made in reducing the annual toll. But the beginning is very small, and if we cannot do better than that we shall remain a long way from victory.

It is often said that cancer is a disease of old people, and that the high total of deaths from it is less important for that

reason. But the Registrar-General's figures show that nearly one-half (29,000) of cancer deaths occur between the ages of 45 and 65—that is to say, at the time when parents have families in course of education and when business and professional responsibilities are at their greatest. It is often also urged that the struggle against cancer is less important than the struggle against infective and nutritional diseases, because these are a more hopeful field of activity and younger lives may be saved by efforts directed against their causes. To this the answer must be that the struggle against all of them must go on side by side, and, indeed, if we are properly organized each will help the other: of that I shall have something to say later.

What is the thesis that I would put before you? It is this: I believe that cancer can be conquered, but that we shall not conquer it until we replace the old type of military campaign by Total War—that is, war in which all modern methods of attack are used for all they are worth, and in which everyone in the nation joins in the effort to secure success. Now, I want to make it clear that, with our knowledge in its present state, I do not pretend that we can prevent all deaths from cancer, but I do claim that if all cases were recognized early, and treated promptly and efficiently, nearly half—that is to say, some 30,000 people in England and Wales—would be saved from death by this disease each year. I claim, too, that the discoveries that have been made during the last ten years give good grounds for hoping that the hard core of the other half will yield to further well-planned and intensive research.

Recognition of Early Symptoms

May I describe to you the total war that I envisage? Cancer starts in every case with a single cell or group of cells in the body that revolt, as it were, against the general system. Instead of quietly performing their functions as they should, these cells take on a rogue's growth that not only is of no use to the patient but ultimately destroys the function of the organ in which they occur, and they gradually extend beyond it to the neighbouring organs till they cause the patient's death. These rogue cells may start in almost any tissue of the body, so that the recognition and treatment of cancer must form a part of the work of many specialists, such as general surgeons, gynaecologists, laryngologists, and others. The disease at its beginning is a small patch localized to one part of the body, and if it is recognized in that state it can generally be surgically removed or be destroyed by irradiation, with an assurance that it will not come back. If not recognized in that early stage it becomes much more difficult to remove completely, and if any of it is left behind the disease will surely recur—and the treatment of recurrences is much less successful than treatment in the earlier stage of the disease.

There is another reason why it is important to recognize cancer early, and that is that after the disease has been present some time bits of the growth break away and are carried by the circulation to distant parts of the body, where they lodge, and such bits may cause secondary growths similar to the one which started the trouble. Such secondary growths are often

* A paper read at the annual meeting of the Notts Branch of the British Empire Cancer Campaign.

complaint at my "Post-war Pension" but I eagerly await just half a day's work. Like the athlete I should like to get into training and gradually increase the pace, so that I can fit myself for the full-time occupation, in civil life, when once again I can enjoy my work.—I am, etc.,

"R.A.F. UNEMPLOYED."

Demobilized Doctors as Assistants

SIR,—I was interested in the correspondence about assistants, and also in arrangements for the settlement of returning Service doctors. A friend of mine applied for and got an assistant-ship last January, after leaving the Army. There was to be a trial period of six months. At the end of this period the principal announced that he could no longer afford an assistant. He made no suggestion that my friend was unsuitable. Now he had got an assistant for the worst period, and also a holiday for himself for three weeks without having to pay a locum. I would be glad if you would publish this letter as a warning to other Service doctors who might be caught the same way. I would also like to comment on the remark by Dr. Vaughan Jones that practices were available for returned Service men at reduced premiums. I have not found it so. If Dr. Vaughan Jones reads the advertisements in the *Journal* he will see for himself the colossal premiums asked for doctor's houses. I feel strongly that the returned Service doctor should get more consideration. I am sure that the medical profession as a whole would wish it so, but this cannot be done by misleading statements.—I am, etc.,

EX-SERVICE ASSISTANT.

Association Notices

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1947. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy child-bearing. It will be awarded for the best essay submitted in competition, competitors being left free to select the work which they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1947, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946.

Diary of Central Meetings

JULY

23. Tues. Council, 10 a.m.
Annual Representative Meeting, 2 p.m. (and succeeding days).
24. Wed. Annual General Meeting, 12.30 p.m. (The first meeting of the new Council will be held at the close of the A.R.M.)

Branch and Division Meetings to be Held

SOUTHAMPTON DIVISION.—At Royal South Hants and Southampton Hospital, Southampton, Wednesday, July 17, 8.30 p.m. Annual general meeting.

Meetings of Branches and Divisions

MONMOUTHSHIRE DIVISION

Lady Florey gave a B.M.A. Lecture on penicillin to a meeting of the Monmouthshire Division on May 16, Dr. G. R. Strong presiding. She began by saying that there were a very large number of publications on penicillin—on the treatment of gonorrhoea there were some 900 alone—but even so, the fundamental properties of the drug as given in the earliest publications had not been contradicted. Penicillin did little harm to the human being and caused no toxic symptoms. Any dose could be given; there was a basic dose for infection, but over and above that it did not really matter

what was given. It could be destroyed by heat, by acid (which was why it was not given by the mouth), and by oxidizing agents. It could not be used in combination with chlorides, as they neutralized its effect. It was itself destroyed by bacteria, which could be combated by keeping it protected from the air. Preparations used for local administration were kept covered and then changed once a week; creams or solutions ran the risk of deterioration; powder contained a sulphonamide and were kept in a refrigerator. Success with penicillin depended on access being obtained to the part to be treated. By giving it intramuscularly every part of the body could be reached via the circulatory system—e.g., a retained placenta or a blood clot. This might stop some of the infection, but it would not get into the placenta and the condition was liable to flare up if penicillin was applied locally, as in impetigo, the root of the infection would not be reached, only the scab. The dose for systemic treatment, irrespective of how it was introduced, was 120,000 units in 24 hours. If given intramuscularly it should be divided into 8 doses of 15,000 units every 3 hours. For a breast abscess 60,000 units should be given twice a day. A pleural effusion should be aspirated and an injection of 240,000 units given every two days. A dose of 500 units per gramme would produce a much higher concentration on the surface if given locally than if given intramuscularly. The intramuscular method of administration came into force after D-day, when larger supplies of the drug were available; infiltration, which had to be carried out in an operating theatre was then almost forgotten. Insufflation might dry the wound, and if the skin surface was infected a crust would be formed and the infection kept below it. It was, however, extremely useful in a small surface wound, but should not be used for a sinus. In cases of pneumonia or osteomyelitis we had been using drugs which were antipyretic—sulphonamides—and the temperature was brought down but the infection was not necessarily controlled. With penicillin the temperature came down slightly after a week; but it was better to watch the patient than to watch the temperature, because even though pyrexia remained the infection was improving.

The lecture, which was well attended, was very much appreciated and many questions were asked. A vote of thanks was proposed by Dr. Grahame Jones and seconded by Dr. Hastings and carried with acclamation.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tues., 5.30 p.m. Ballot for election to the Fellowship.

Section of Proctology.—Wed., 5.30 p.m. Annual general meeting: Election of Officers and Council. Discussion: Some Peculiarities in the Surgical Pathology of Malignant Disease of the Ano-recta Region. Opener: Dr. Cuthbert Dukes, followed by Mr. Kenneth James: Surgical Complications of Amoebic Dysentery.

BIOCHEMICAL SOCIETY.—At Department of Biochemistry, University New Buildings, Teviot Place, Edinburgh, Fri., 10.30 a.m. Communications and demonstrations.

MACKENZIE INDUSTRIAL HEALTH LECTURE.—At B.M.A. House, Tavistock Square, W.C., Wed., 5.45 p.m. Dr. Donald Hunter: Academic Aspects of Industrial Medicine.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tues., 5 p.m. The Bertram Louis Abrahams Lecture by Prof. C. A. Lovatt Evans, F.R.S.: The Outlook of Physiology To-day.

APPOINTMENTS

TREISSMAN, H., F.R.C.S., D.O.M.S., Honorary Ophthalmic Surgeon, King Edward Memorial Hospital, Ealing.

WINCHESTER: ROYAL HAMPSHIRE COUNTY HOSPITAL.—Honorary Assistant Surgeons: J. Rubin, F.R.C.S.Ed., P. W. Ingram, F.R.C.S.Ed. Honorary Medical Officer in Charge of X-ray Department: R. I. Roberts, M.R.C.S., L.R.C.P., D.M.R. Honorary Orthopaedic and Traumatic Surgeon: G. N. Golden, F.R.C.S. Honorary Psychiatrist: W. L. Neustatter, M.D. Honorary Assistant Eor, Nose, and Throat Surgeon: G. S. Midgley, M.R.C.S., D.L.O.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BURFIELD.—On June 26, 1946, at Kampala, Uganda, to Phemie (née Child), wife of Dr. G. A. Burfield, Colonial Medical Service, Bukoba, Tanganyika Territory, a daughter.

STALEY.—On July 2, 1946, at the Osborn Nursing Home, Thetford, to Bill (née Williams), wife of Dr. G. R. Staley, M.B., B.S., a daughter—Anne.

DEATHS

ADAMS.—On June 27, 1946, very suddenly, Dorothy Mann Adams, M.B., B.Ch., late R.A.F.V.R., greatly beloved sister of Ursula Price, Sloane House, Seaford, Sussex.

LOUGHLIN.—On May 27, 1946, suddenly, at his home, Beeton Corner, Barton-on-Sea, Dermot Loughlin, D.Sc., M.B., B.S.Lond., late of Saxonhurst, Woolston, aged 60.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. Christopher Hardwick at Nuffield House, Guy's Hospital, S.E.1.; Mr. P. H. Newman, F.R.C.S., at 66, Harley Street, W.1. (Langham 3808).

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 20 1946

TOTAL WAR ON CANCER*

BY

G. F. STEBBING, M.B., B.S., F.R.C.S., F.F.R.

Hon. Secretary, Radium Commission

As we have to make war on cancer is no new idea. Indeed, the British Empire Cancer Campaign in its title makes use of a military term, for the first meanings of "campaign" in the Oxford English Dictionary are: A series of military operations in a definite theatre with one objective; organized course of action.

Up to the beginning of the war of 1914-18 the idea in most people's minds was that war was a business for the fighting forces of the opposing countries, and it was a rude shock for any of us to find that the line between the fighting forces and the civilians was not very clearly defined, and that before the conflict was ended a large number of civilians had had to play an important part in the effort for victory. The war that has recently ended has made it clear to everybody, in every nation, that hostilities are no longer the concern only of the military forces but that every man, woman, and child on each side is exposed to the dangers of the fighting and must play a full part in the complex activities necessary to enable victory to be achieved.

An Insidious Foe

When our Campaign was started it was realized that our foe, cancer, was an insidious and mysterious foe, and that if we were to overcome it we should have to organize a series of operations on a wide scale in a definite field and with the objectives of discovering the cause of and finding a cure for cancer. It was envisaged that the soldiers who would do the fighting were the scientists in the laboratories and the doctors in the consulting-rooms and operating theatres, and that to keep them at work under the best conditions they must be helped by an organization that would provide laboratories and hospitals with whatever funds were necessary to carry on the war. It was a campaign such as we were familiar with in the military sense in those days, and some notable victories were won. Some of the causes of cancer have been ascertained, and some methods of treatment of great value have been evolved: these represent battles that have been won; but the war goes on, and we are still a long way from victory.

The Registrar-General states that 600,000 people died in England and Wales during 1944, that 71,814 of these were afflicted as having died of cancer, and he tells us that cancer is the second commonest cause of death. There is a very important thing to note about this figure: since the Registrar-General began to analyse the causes of death the number of deaths attributed to cancer increased slowly but surely every year until 1944, and in that year, for the first time, the number was smaller than in the year before—smaller by 226. Many factors have to be taken into consideration, but there is reason to hope that this may mean the turning of the tide, and that a small beginning has been made in reducing the annual toll. At the beginning is very small, and if we cannot do better than that we shall remain a long way from victory.

It is often said that cancer is a disease of old people, and that the high total of deaths from it is less important for that

reason. But the Registrar-General's figures show that nearly one-half (29,000) of cancer deaths occur between the ages of 45 and 65—that is to say, at the time when parents have families in course of education and when business and professional responsibilities are at their greatest. It is often also urged that the struggle against cancer is less important than the struggle against infective and nutritional diseases, because these are a more hopeful field of activity and younger lives may be saved by efforts directed against their causes. To this the answer must be that the struggle against all of them must go on side by side, and, indeed, if we are properly organized each will help the other: of that I shall have something to say later.

What is the thesis that I would put before you? It is this: I believe that cancer can be conquered, but that we shall not conquer it until we replace the old type of military campaign by Total War—that is, war in which all modern methods of attack are used for all they are worth, and in which everyone in the nation joins in the effort to secure success. Now, I want to make it clear that, with our knowledge in its present state, I do not pretend that we can prevent all deaths from cancer, but I do claim that if all cases were recognized early, and treated promptly and efficiently, nearly half—that is to say, some 30,000 people in England and Wales—would be saved from death by this disease each year. I claim, too, that the discoveries that have been made during the last ten years give good grounds for hoping that the hard core of the other half will yield to further well-planned and intensive research.

Recognition of Early Symptoms

May I describe to you the total war that I envisage? Cancer starts in every case with a single cell or group of cells in the body that revolt, as it were, against the general system. Instead of quietly performing their functions as they should, these cells take on a rogue's growth that not only is of no use to the patient but ultimately destroys the function of the organ in which they occur, and they gradually extend beyond it to the neighbouring organs till they cause the patient's death. These rogue cells may start in almost any tissue of the body, so that the recognition and treatment of cancer must form a part of the work of many specialists, such as general surgeons, gynaecologists, laryngologists, and others. The disease at its beginning is a small patch localized to one part of the body, and if it is recognized in that state it can generally be surgically removed or be destroyed by irradiation, with an assurance that it will not come back. If not recognized in that early stage it becomes much more difficult to remove completely, and if any of it is left behind the disease will surely recur—and the treatment of recurrences is much less successful than treatment in the earlier stage of the disease.

There is another reason why it is important to recognize cancer early, and that is that after the disease has been present some time bits of the growth break away and are carried by the circulation to distant parts of the body, where they lodge, and such bits may cause secondary growths similar to the one

* A paper read at the annual meeting of the Notts Branch of the British Empire Cancer Campaign.

numerous, and are liable to occur in places whence surgery cannot remove them, and where treatment by irradiation is difficult.

To obtain the best results with our present knowledge we have to recognize cancer in its earliest stages, and that is not easy. Often the earliest symptom is some interference with our normal functions, and such derangements are caused by many things besides cancer. In fact, disorders of function are much more commonly due to simple causes than to cancer, and it is for this reason that cancer is so often overlooked. In deeply seated cancers the early diagnosis can often be made only after an examination by a team of experts each of whom plays his or her part in a well-directed scheme.

Co-ordination of Effort

Total war cannot be waged by various individuals working on their own and holding little communication with each other. There must be a responsible person to co-ordinate the work of innumerable specialists and to direct their efforts towards the desired end.

Experience which has been gained during the last fifteen years or so has shown that an organization for the diagnosis and treatment of cancer is most likely to be efficient if it deals with a population of two to four million people. Such a number will provide enough cases of cancer in the different sites of the body to make expert those who have to handle them, and yet will not be too unwieldy to organize. The headquarters of such an organization must be in, or in close relation to, a general hospital which is staffed and equipped to deal with every kind of work, and be closely associated with a medical school and faculty of a university; for not only must research be carried on in every cancer organization but the stimulating atmosphere of the teaching school should be recognized as a valuable asset.

On the headquarters staff there must be specialists of every type, who, though not devoting their whole time to the treatment of cancer, should have a wide experience of it. For the early recognition of the disease there must be consultation clinics, in which surgical specialists, radiotherapists, radio-diagnosticians, pathologists, and biochemists all have their part to play; and to get the best results such specialists should have frequent consultations, for preference in the patient's presence. Treatment of the patient should be fully planned before it is begun, and be carried out by those members of the staff best able to do it. At the headquarters clinic, arrangements must be made for dealing with all difficult cases sent in from the periphery, and the person responsible for the co-ordination of the work must see that there is no delay at any stage. As soon as cancer is suspected in anyone anywhere in the region, examination and any necessary consultation must be arranged, and treatment started at once. A month or two of delay may cost a life.

The organization of hospital work these days is very complex, and even teaching hospitals cannot all have every one of the special departments needed for the treatment of cancer; but there must be effective and close co-operation between the headquarters and such units as neurosurgery, thoracic surgery, plastic surgery, orthopaedic surgery, etc. In the treatment of cancer, surgery and radiotherapy should play about an equal part; sometimes the one is the better, sometimes the other, but in many cases both are needed to get the best results. Surgery has a double part to play, for the diagnosis can often be made only by operation and the aid of the pathologist, whose department should be intimately associated with the organization.

In the headquarters unit there must be a fully equipped and staffed radiotherapeutic unit. Radiotherapy is still a young science, having been introduced less than half a century ago, and modern methods of radiotherapy in this country are less than twenty years old. Its practice requires specialists who devote the whole of their time to it and who have at their command enough apparatus to make sure that they can give to the patient the treatment that is best suited to him at the time he will benefit most. In practice this means that they must have at least four or five different sets of x-ray therapy apparatus for routine use, and two or three for experimental work. They must have a gramme or more of radium and either a radium beam or a supervoltage apparatus. They must also have the

assistance of two or more physicists specially trained in hospital work and provided with all the laboratories and workshops they need. There is a great expectation that the discoveries which became public when the atomic bomb was used will play a great part in the future of medicine, and particularly in the treatment of cancer. There is some danger that too much may be expected of the benefits to be derived either in industry or in medicine from recent discoveries in nuclear physics, but it is quite clear that without a great deal of research we shall not know how much use atomic physics may be in medicine, and that research will have to be done in a large measure by men who are actively engaged in the treatment of patients and who know the problems that have to be solved. The radiotherapists, the physicists, and the biochemists will have to be equipped to take advantage at once of any discoveries that are made.

The work of the cancer organization will not be confined to the headquarters unit. A few large hospitals in the region must be staffed and equipped to carry out treatment by surgery, and one or two of them to provide radiotherapy. It is important that the work should be done only in hospitals large enough to have specialists of all types and all the skilled staff and equipment which modern treatment needs.

I have said that surgeons dealing with cancer should not devote the whole of their time to its treatment. Such a limitation of their experience would not produce the best results. It is desirable, however, that surgeons (and in that term I include all surgical specialists such as laryngologists, gynaecologists, etc.) dealing with cancer should have the opportunity of becoming expert by handling large numbers of cases. To this end the cancer patients should be so distributed that each member of the staff will deal with one or two types of the disease only, instead of each of them trying to deal with all types.

Diagnostic Clinics

In addition to the hospitals where cancer is treated there must be a larger number at which patients can attend for preliminary investigation if their family doctors suspect the possibility of cancer. It is desirable that arrangements be made for doctors to attend such clinics with their patients. Such clinics should be attended by the specialists on the staff of the cancer organization who are actively engaged in the treatment of cancer. These diagnostic clinics may be used also for the purpose of following up treated patients so that they may be periodically examined. The cancer organization must not stop, however, at the hospitals that take part in its work. Our war will not be total unless the family doctor is a part of it and patients are aware of its existence and willing to play their part.

Although cancer is the second commonest cause of death it is not a common disease. That paradox arises from the fact that hitherto most patients who develop a cancer have (I think quite unnecessarily) died of it, whereas in most other diseases the majority of sufferers get well. So it comes about that a family doctor sees many cases of tonsillitis, pneumonia, etc., every year but not many cases of cancer. Dividing the number of cancer deaths evenly among the doctors in general practice means that each would see only about two cases a year. But the doctors in general practice have got to suspect cancer many times a year if they are not going to miss the early case, and we want a well-worn path from every doctor's surgery to the diagnostic clinic, whether it be at the headquarters hospital at one of the large treatment centres, or at a hospital providing only a preliminary investigation centre. If the family doctor is to be enabled to play his part in the total war he must be in constant communication with the organization, he must receive a report of all investigations and periodic reports of treatment and its results, and he must be encouraged to help in securing the regular follow-up and re-examination of patients at the proper times.

This constant and close association of the family doctor with the cancer organization is essential for the success of our total war, but it will serve another purpose, to which I have already made a brief allusion. I have said that if the growth is detected early the general practitioner has got to suspect cancer in many patients for every one that actually has it. He must have it in mind whenever he sees a patient complaining of

ordered function the cause of which is not revealed by the methods of investigation as he can apply. If such a case referred to the cancer organization for full examination and nearer is not found, a diagnosis of some other disease will be made, and our war on cancer will, in such cases, help on our fight against other less lethal but very troublesome diseases.

But the patient too has a duty. He must not put off reporting to his doctor any disturbance of function that lasts more than a few days. He must let him decide whether the disturbance is such that it requires further investigation, and if the doctor seems to make light of it at the first visit he must not be deterred from going to him again if the disturbance persists.

It is one of the characteristics of human nature that when we are afraid of a thing we tend to shy away from it, to put it off, although we know that sooner or later this will have to be done. This leads some people to postpone their visit to the doctor for fear of what he may tell them. To overcome this fear is the patient's part in the total war, just as it is the family doctor's part to use that well-worn path to the diagnostic clinic whenever a suspicious symptom presents itself.

An organization such as I have described does not run itself—it needs an elaborate mechanism. The person charged with the co-ordination of it should be a medical man with a lifelong experience of cancer. He must have a technical committee on which specialists and general practitioners should be represented, and he should see that there is frequent consultation and discussion between all those who are engaged in the diagnosis and treatment of cancer in the region. He must see that there are adequate bed accommodation and proper equipment for all kinds of treatment; he must see that the secretarial services are such that every clinician is given clerks to enable him to take adequate notes, and that doctors throughout the region are kept fully informed about their patients; he must see, too, that there is a statistical bureau under a trained statistician to analyse the work of the organization and the results obtained; he must be in touch with pathological, physical, and biological research and give the workers in the organization an opportunity of hearing of and discussing new discoveries; he must see that the existence and purpose of such an organization are known to all doctors and patients in his region; and he must study the methods best calculated to secure the objects of the organization—that is, the early recognition and prompt treatment of cancer.

Care of Patients in the Late Stages of Cancer

But when all that is done we have not finished. For many years to come there will be a number of patients who, because of their own neglect or the failure of our organization or the limitation of our knowledge, reach a stage in which they still have cancer and cannot be further benefited by surgery or radiation. We are cowards if we shut our eyes to the existence of these. Much can be done to lessen their sufferings, and the cancer organization should be charged with the duty of providing for their care and treatment, whether it be at their own homes, in nursing homes, or in hospital wards; they should be under constant review by the members of the organization staff by whom they were, or might have been, treated, so that comfort may be provided for the patient and education for the staff. And here I would like to stress the great importance of obtaining post-mortem examinations on all who die of cancer or suspected cancer. The pathological department has the duty of helping greatly in diagnosis by the microscopical examination of small pieces of tissue removed at operation. The accuracy of such diagnosis is greatly increased if the pathologists of the organization have the opportunity of making careful post-mortem examinations; and often the causes that have prevented successful treatment can then be found. During the late war our patients did not hesitate to expose their living bodies to danger when the drive for victory needed it. Should they not now allow their dead bodies to be used to help our total war on cancer?

Two years ago Prof. Dodds, at the Annual Meeting of the British Empire Cancer Campaign, reported the startling, and favourable, results that had been obtained in the treatment of one type of cancer by synthetic hormones. This is the first

example of the combat of a cancer by such means, but it is almost certain that it will be followed by other successes on the same lines, and many cases that are untreatable now will then become treatable.

Research

I must say a word or two about research. Every cancer organization, if it is to play its full part in the total war, must have a research department, which should have the advantage of working in close association with the scientific faculties of a university. Our ideas about the medical faculties of universities are rapidly enlarging as we realize that if our medical services are to be efficient the university must continue to educate the graduate after it has finished educating the undergraduate. To that end many hospitals not now intimately associated with the medical schools will have to take part in continuing the education of the newly qualified and providing refresher courses for the older graduates. The research department should be in very close touch with the medical staff of these hospitals, so that the line, which is at present undesirably broad, between laboratory research and clinical research should become less clearly defined. It is quite obvious that discoveries made in the laboratory have not served any useful purpose until they have become known to and been used by the doctors who are treating patients. It generally takes some years before discoveries such as penicillin, or the hormone used by Prof. Dodds, are widely and successfully employed in the treatment of patients who may benefit by them. It should be one of the functions of our organization that when such discoveries are made they should be readily available to all sufferers from cancer who might benefit by them.

Conclusion

Such an organization is what I mean by "total war on cancer." It sounds very elaborate and must be very expensive. It is; but remember that the object is to save much suffering and 70,000 lives a year. We shall not save them all for many years to come, but I believe half of them could be saved now, and the British Empire Cancer Campaign has a very honourable reputation for that kind of research which will in the long run, I believe, lead to ultimate complete victory.

The Cancer Act, 1939, had in view the provision of such organizations to cover the whole country, but it is to be regretted that the war has caused its operation to be repeatedly postponed. Here in the East Midlands you have an organization in process of being formed; and the Nottingham General Hospital, with the Sheffield Royal Infirmary, Leicester Royal Infirmary, and Derbyshire Royal Infirmary, are cast to play the leading parts under the auspices of Sheffield University.

Whatever shape the National Medical Service may take, it should make easier the co-ordination of medical work over the whole region of the East Midlands. But these activities of the State, however necessary they may be in our complicated life, make only a framework in which men and women work. The recent war has shown us the great importance of having, in addition to State direction, State control, and State enterprise, voluntary bodies such as the British Red Cross and the Order of St. John of Jerusalem, which devote their time and attention to filling in those gaps that always exist in bureaucratic schemes. State concerns lack so many of the virtues which voluntary bodies can possess. In the winning of our total war against cancer I pin my faith to that enthusiasm and voluntary effort of which your branch of the British Empire Cancer Campaign is a shining example.

After long delay caused by printing difficulties the Rothamsted Experimental Station has published a pamphlet recording the centenary celebrations on July 1, 1943. This opens with an account of the work and history of the departments by the director, Sir John Russell, F.R.S. Addresses were given by the chairman, the Earl of Radnor, and the then Minister of Agriculture, Mr. R. S. Hudson; and a letter was read from the Duke of Devonshire paying tribute to the work of Rothamsted. The list of those taking part in the commemoration includes the names of Sir Henry Dale, at that time President of the Royal Society, the late Prof. W. W. C. Topley, F.R.S., secretary of the Agricultural Research Council, and Prof. C. R. Harington, F.R.S., representing the Medical Research Council. The pamphlet also includes messages of congratulation from the Empire and associated countries and from foreign and home sources.

SOME OBSERVATIONS ON LIVER FUNCTION TESTS IN DISEASES NOT PRIMARILY HEPATIC

BY

A. BARHAM CARTER, M.D., M.R.C.P., D.P.M.
Physician, Ashford County Hospital

AND

N. F. MACLAGAN, M.D., D.Sc., M.R.C.P.
Biochemist to Westminster Hospital

(From the Wards and E.M.S. Sector Pathological Laboratory, Ashford County Hospital, Middlesex, and Westminster Hospital Medical School)

The liver is dependent upon a pure and unrestricted blood supply for the normal performance of its many functions. It is therefore not surprising that a proportion of abnormal results with a variety of liver function tests should have been recorded in conditions such as pneumonia (Curphey and Solomon, 1938), heart failure (Bernstein *et al.*, 1942; Chávez *et al.*, 1943), hyperthyroidism (Haines *et al.*, 1939; Lichman, 1941; MacLagan and Rundle, 1940), rheumatoid arthritis (Rawls *et al.*, 1937), glandular fever (Kilham and Steigman, 1942; Davis *et al.*, 1945), after surgical operations (Boyce, 1941), and in therapeutic malaria (Fredericks and Hoffbauer, 1945; Kopp and Solomon, 1943).

Thus while the principal use of liver function tests is naturally in the investigation of gross liver disease, the interpretation of results is also sometimes dependent upon a knowledge of the reaction of the liver to disturbances of a more general nature. For example, the discovery of certain types of functional impairment in a patient with an enlarged liver would ordinarily suggest the probability of cirrhosis, but, if congestive heart failure were also present, then chronic passive congestion of the liver might well explain the findings. A further complication in the case of the flocculation tests is the uncertainty as to their mechanism. Recent work suggests that they depend principally upon changes in the serum gamma-globulin content (Kabat *et al.*, 1943; Moore *et al.*, 1945), and increases in this fraction are not confined to liver disease, but may occur in conditions such as rheumatic fever, aplastic anaemia, and peritonitis (Longworth *et al.*, 1939). Moreover, many circulating antibodies are known to occur principally in the gamma-globulin fraction (Enders, 1944).

The possibility of false positive reactions is therefore a real one, although this has not seriously interfered with the application of these tests to the study of liver disease in the case of cephalin-cholesterol (Hanger, 1939), the serum colloidal-gold (Gray, 1940; MacLagan, 1944a), and the thymol turbidity tests (MacLagan, 1944b). This type of interference appears, however, to be more common with the Takata-Ara reaction (Magath, 1940).

The above considerations suggested to us that it would be worth while to define more closely the nature and degree of the abnormalities likely to be encountered in certain conditions not primarily involving the liver, using the two flocculation tests—the serum colloidal-gold reaction and the thymol turbidity test—which we had found of particular value in the diagnosis of gross liver disease. Qualitative tests for urinary urobilin were also used as a confirmatory procedure.

Methods

The serum colloidal-gold test was performed as previously described (MacLagan, 1944a). Normal serum gives a negative result with this test—recorded as 0 in the tables below—and 5+ is the strongest positive. The thymol turbidity test (MacLagan, 1944b) is expressed in units, normal limits being 0 to 4. Urine urobilin tests were made by spectroscopic examination with a direct-vision hand spectroscope, using a 1-in. (2.5-cm.) layer, after converting urobilinogen to urobilin by the addition of a few drops of iodine 1% solution and acetic acid. Particular care was taken to obtain fresh afternoon specimens and to mix any deposit thoroughly with the main bulk before testing.

Material

The diseases chosen for the study were originally those which liver involvement had been reported by others (heart failure, glandular fever, rheumatoid arthritis), but accidental positive findings led to the inclusion of malaria and infective endocarditis. The material is shown in detail in Table I,

TABLE I.—Summary of 123 Cases Tested

Diagnosis	No. of Cases	% Gold-positive	% Thymol-positive
Malaria	35	94	80
Rheumatoid arthritis	34	76	38
Heart failure	28	39	36
Glandular fever	19	95	58
Subacute bacterial endocarditis	7	100	86

represents the admissions of the relevant types of illness to Ashford (formerly Staines) County Hospital during the two years. In addition to these, 42 further cases shown in Table II were used as controls to exclude fever and joint

TABLE II.—42 Control Cases

Diagnosis	No. of Cases	No. Gold-positive	No. Thymol-positive
Pulmonary tuberculosis	18	1	1
Acute articular rheumatism	8	0	0
Infective arthritis	6	3	0
Osteo-arthritis	10	0	0

changes as possible contributing factors. The results in the control cases were mainly negative, the only positive reaction being one patient with pulmonary tuberculosis (gold, 3; thymol, 7 units) and three with infective arthritis (all gold thymol-negative). It would appear, therefore, that the positive results recorded below are not directly related to pyrexia or joint involvement.

Results

The results will be discussed under five headings.

1. *Congestive Cardiac Failure.*—Twenty-eight consecutive cases of marked congestive failure with gross oedema and hepatic enlargement were examined. The ages of the patients were from 25 to 70 years, and the aetiology of the failure was rheumatic carditis, 10; arteriosclerotic hypertension, coronary thrombosis, 3; pulmonary disease, 4. The results of the investigation are shown in Table III. Analysis of the

TABLE III.—Congestive Cardiac Failure (28 Cases)

Thymol Units	Gold Test						Tot
	0	1+	2+	3+	4+	5+	
0-4	17	0	0	0	1	0	1
5-7	0	2	1	4	0	2	1
8-15	0	0	0	0	0	1	1
Totals	17	2	1	4	1	3	28

39% gold-positive; 36% thymol-positive.

results showed no significant correlation between positive findings and size of liver, length of history, or aetiology of failure. The only suggestive finding was in regard to prognosis as death occurred in all the 8 markedly positive cases within four months, compared with 4 deaths out of the 17 negative cases in the same period. In 15 cases the urine was tested for urobilin, which was present in 8. All with positive flocculation reactions had urobilinuria, and it was present in 5 of those with negative reactions. The presence of urobilinuria therefore appears to be a more sensitive test of liver function in this condition. Of the two flocculation tests used, the gold and thymol seemed equally sensitive, being positive in 39% and 36% cases respectively.

2. *Malaria.*—Thirty-five consecutive cases of relapsing benign tertian malaria in young soldiers were investigated. The diagnosis was confirmed in every case by the finding of *Plasmodium vivax* in the blood smear. The results are shown in Table IV. A very high proportion gave positive results, gold being rather more sensitive than the thymol (94% and 86% respectively). Urobilinuria was present in 20 out of the

cases in which the test was carried out, but may well have been due in part to accompanying haemolysis. The temporary nature of the disturbance in this condition was shown by the repetition of the tests in 7 cases, in which a return to normal or nearly normal results was found after three weeks' treatment.

TABLE IV.—*Malaria (35 Cases)*

Thymol Units	Gold Test						Totals

Totals ..	2	4	6	9	11	0	35

94% gold-positive; 80% thymol-positive.

3. *Glandular Fever*.—Nineteen cases of this condition were investigated, and the diagnosis was based in every instance on the clinical picture, the presence of abnormal mononuclear cells in the circulating blood, and a positive Paul-Bunnell reaction in a dilution of at least 1 in 64. The results are shown in Table V, where they are arranged in order of descending

TABLE V.—*Glandular Fever (19 Cases)*

Paul-Bunnell Titre	Thymol Units	Gold Test	Total Leucocytes per c.mm.	Atypical Mononuclears per c.mm.

64	1	1+	7,000	950

95% gold-positive; 58% thymol-positive.

Paul-Bunnell titres. The thymol and gold reactions were both markedly positive in all the cases with high Paul-Bunnell readings and with an atypical mononuclear count of over 4,000. Urobilinuria was present in only one case, which was also clinically jaundiced.

This patient showed a very interesting correlation between clinical course and biochemical tests. She was an A.T.S. girl, aged 25, who came into hospital jaundiced and was thought at first to be a case of infective hepatitis with splenomegaly. Very few cervical glands were palpable and none elsewhere. Her blood count showed 15,000 leucocytes with 3,200 abnormal mononuclears, and the Paul-Bunnell test was positive in a dilution of 1 in 256. The liver function tests showed a thymol of 6 units, a colloidal gold of 2+, and a serum alkaline phosphatase of 25, with 6 units (Watson) of urobilin in the urine—results typical of infective jaundice. Her jaundice improved, but a week later axillary and inguinal glands became palpable and tender, her jaundice deepened once more, and the character of the reactions changed. The thymol was now 5 units, colloidal gold 0, and phosphatase 46, and urobilin was absent from the urine—results typical of obstructive jaundice. Recovery ensued. The course of the illness, correlated with the biochemical findings, suggests that the mechanism of jaundice in this condition may vary.

Thus Davis *et al.* (1945) have recently described, in necropsy material from a typical case of glandular fever, liver changes indistinguishable from those of infective hepatitis, and one of us has suggested that jaundice could occur in this condition from obstruction to the common bile duct by glandular enlargement in the porta hepatis (Carter, 1942). In the present case the initial jaundice was probably infective in origin and the exacerbation obstructive.

Taking the group as a whole, it appears that the flocculation tests are closely correlated with the abnormal mononuclear count and the Paul-Bunnell test in glandular fever.

4. *Subacute Bacterial Endocarditis*.—Seven proved cases of this condition, with a typical clinical picture, previous valvular

damage, embolic phenomena, and positive blood culture, were investigated. In addition, 5 other cases were examined in which the condition was suspected because of fever and evidence of endocarditis, although a negative blood culture persisted without embolic phenomena. In these 5 cases the diagnosis was eventually abandoned. The results are shown in Table VI. The

TABLE VI.—*Subacute Bacterial Endocarditis (7 Cases)*

Gold test ..	7 Proved Cases							5 Suspected Cases Subsequently Disproved			
	Thymol units ..	5+	5+	5+	5+	4+	3+	3+	1+	0	0
5+	8	5	5	5	5	4	3	3	4	0	2

Of proved cases 100% were gold-positive and 86% thymol-positive.

almost uniformly positive results in the proved cases are striking in spite of their small number. Urobilinuria was present in only 2 out of these 7 cases. As a positive blood culture is not always easy to obtain quickly, the flocculation tests may have some diagnostic value in this condition and allow of treatment at the earliest opportunity. In the 5 negative suspected cases the tests were of considerable help, as illustrated by the following:

A man aged 30, with a rheumatic history, was admitted with irregular pyrexia, microcytic anaemia, tachycardia, and the signs of a mitral stenosis. He developed haematuria of a mild but persistent nature, a rising blood urea, and albuminuria without oedema. This condition subsided, and was followed by auricular fibrillation of paroxysmal type. The fever persisted and a cerebral embolism occurred. A confident diagnosis of bacterial endocarditis would have been clinically justified, but flocculation tests and blood culture remained negative. The patient slowly recovered with salicylates and iron, and was well eighteen months later except for his valvular defect, presumably having had a severe reactivation of his previous rheumatism. In one of the proved cases the patient appears to have recovered a year after his first treatment with penicillin, and there has been an interesting change in his flocculation reactions:

Mar. 13, 1945	Thymol, 6 ; Gold, 5+
April 31, 1945	Thymol, 5 ; Gold, 5+
June 30, 1945	Thymol, 3 ; Gold, 1+
Oct. 30, 1945	Thymol, 2 ; Gold, 0
Jan. 6, 1946	Thymol, 2 ; Gold, 0

A comparison between the gold and thymol tests in the group shows a considerable difference in degree of sensitivity in favour of the gold, although the thymol reaction was just positive in 6 out of the 7 cases with positive gold reactions.

5. *Rheumatoid Type of Polyarthritis*.—This series consisted of 34 patients (30 women) who showed an atrophic type of polyarthritis ranging from the classical rheumatoid arthritis to a mild, fleeting, periarticular, inflammatory reaction with minimal radiological changes. The results are shown in Table VII. In

TABLE VII.—*Rheumatoid Arthritis (34 Cases)*

Thymol Units	Gold Test						Totals
	0	1+	2+	3+	4+	5+	
0-4	8	5	2	4	1	1	21
5-7	0	2	2	1	3	0	8
8-15	0	0	0	0	1	4	5
Totals ..	8	7	4	5	5	5	34

76% gold-positive; 38% thymol-positive.

the whole group there was a marked difference between the gold test (76% positive) and the thymol test (38% positive). Urobilinuria was present in only 1 out of 19 cases tested. The series divides itself up into four classes:

(1) The very advanced long-standing typical rheumatoid arthritis with permanent deformity and gross generalized radiological changes. There were 4 of these, all with markedly positive colloidal gold reactions and very little change in the thymol turbidity test.

(2) The active classical rheumatoid arthritis, with involvement of wrists, fingers, knees, and feet, with spindling of fingers, atrophic radiological changes, and raised erythrocyte sedimentation rate. There were 16 in this group, with 1 man among them, and 4 of the cases showed Felty's syndrome with generalized superficial lymphatic glandular enlargement and splenomegaly; 11 of these had a markedly positive colloidal gold reaction, 3 were weakly positive, and 2 were negative.

(3) Ten cases with a history of fibrositic pains, occasional peripheral joint swellings, a minimal degree of finger-spindling, and some general osteoporosis around the affected joints, but no other joint changes. The sedimentation rate was raised in all, and a diagnosis of probable early rheumatoid arthritis was made. All these patients were between 20 and 30 years of age. Two showed a spondylitis with stiffness and pain, but no changes in radiological appearances of spinal or sacro-iliac joints. Two were associated with thyrotoxicosis. The colloidal-gold findings were: 1 markedly positive (3+), 1 positive (2+), and 8 weakly positive (1+).

(4) Four cases with atypical findings, usually fleeting joint pains and swellings, without spindling, with raised sedimentation rates, and radiological changes showing only a minimal bone rarefaction. All these had negative gold and thymol reactions.

In the whole group there was a rough though definite correlation between the gold test and the sedimentation rate, as shown, in the accompanying Chart. It will be seen from this

Chart showing the correlation between the serum colloidal-gold reaction and the sedimentation rate in 34 cases of rheumatoid arthritis

that all cases with 3+, 4+, or 5+ gold reaction had sedimentation rates over 25 mm. in 1 hour and that all cases with a negative gold reaction had rates below 20 mm.

Taking the rheumatoid group as a whole, it will be seen that the gold test was positive in 28 out of 30 cases in which the diagnosis was well established. The thymol test was much less sensitive, being positive in only 13 of these 30 cases. Urobilinuria was almost uniformly absent (18 out of 19 cases).

Discussion

The results as a whole may be considered under three findings.

1. *Heart Failure.*—In this group the positive results are readily explicable on the basis of chronic passive congestion of the liver, and probably are mainly a reflection of this process. With the gold and thymol tests the proportion showing abnormal findings was nearly identical and was similar to that found with other tests by Chávez *et al.* (1943). The presence of urobilinuria in all the positive reactors serves as confirmation of the presence of liver dysfunction in these cases.

2. *Rheumatoid Arthritis.*—The balance of probability here is that the high proportion of positive results is not specifically related to liver pathology, since there was no urobilinuria and the published evidence of liver damage in this disease does not suggest such a degree of dysfunction as would explain the findings. It is possible that an antibody associated with the serum gamma-globulin fraction may be responsible for the flocculating power of patients with rheumatoid arthritis. It is noteworthy that there was a wide discrepancy between the two tests in this group (gold, 76% positive; thymol, 38% positive).

3. *Malaria, Glandular Fever, Infective Endocarditis.*—These conditions form an intermediate group in which there is some supporting evidence of liver disease, but in which it is doubtful whether this explains all the findings. Thus urobilinuria was constantly present in malaria, but may have been partly due to haemolysis; it was mainly absent in glandular fever and inconstant in infective endocarditis. There is histological evidence of hepatitis in malaria and in glandular fever (Lichtman, 1942; Davis *et al.*, 1945), and the latter is known to cause jaundice in a small proportion of cases. However, this jaundice may sometimes be due to enlarged glands in the portal fissure, as suggested by one of us (Carter, 1942) and as illustrated in the case above. In these three conditions the correlation between the tests also occupies an intermediate position (gold, 95% positive; thymol, 74% positive), being less close than in diseases with known liver damage, such as infective hepatitis (MacLagan, 1944b). It seems a reasonable inference

that in these three diseases both liver dysfunction and antibody formation contribute to the results, no doubt in varying degree in different patients.

Conclusion

In conclusion it may be stated that, while these flocculation tests have proved of great value in the investigation of primary diseases of the liver, positive results do certainly occur in certain conditions not usually regarded as liver diseases. This applies particularly to the gold test, the thymol test being rather more specifically related to liver pathology. Diseases such as heart failure, glandular fever, malaria, infective endocarditis, and rheumatoid arthritis must therefore be considered as possible alternative diagnoses in patients with suspected primary liver damage who have positive flocculation tests. Viewed from another angle, we have had some diagnostic help from the tests, particularly the gold test, in rheumatoid arthritis, glandular fever, infective endocarditis, and malaria. Negative results are unusual in these conditions and positive ones of some confirmatory value. The tests may possibly have some prognostic significance in heart failure.

Summary

The serum colloidal-gold test and the thymol turbidity test have been performed in 35 cases of malaria, 34 of rheumatoid arthritis, 28 of congestive cardiac failure, 19 of glandular fever, and 7 of subacute bacterial endocarditis.

Some positive results occurred in each group, the proportion varying from 95% to 39% for the gold test, and from 80% to 36% for the thymol test. The two tests were equally sensitive in heart failure, but the gold test was more sensitive in other conditions, the difference being particularly great in rheumatoid arthritis.

In glandular fever there was a positive correlation between the gold test, the Paul-Bunnell test, and the abnormal mononuclear counts. In rheumatoid arthritis the gold test and the erythrocyte sedimentation rate were positively correlated.

The positive finding in heart failure probably resulted from chronic passive congestion of the liver. In the other conditions both liver damage and antibody formation may have contributed to the results.

The flocculation tests are not purely liver function tests, as they probably depend upon changes in the serum gamma-globulin fraction. They have proved of value as diagnostic aids both in primary liver diseases and in some of the above conditions, but the possibility of occasional interference between the two groups must be considered in interpreting the results.

We are much indebted to Dr. A. G. Signy for the haematological data and Paul-Bunnell tests. Part of the expenses of the work was defrayed by a grant to one of us (N. F. M.) from Westminster Hospital.

The Scottish National Blood Transfusion Association states in its annual report that during the first three months of 1946 hospital demands for blood exceeded the amount given by volunteer donors. Requirements were met only by drawing on accumulated wartime reserves which it had not been necessary to expend during the war. As long as the war was on, an adequate number of volunteers was always ready to come forward to give blood. For peacetime conditions considerably more organized recruitment and propaganda will be necessary if the Association is to meet its commitments to the hospital services.

RHEUMATIC FEVER IN THE R.A.F.

RESULTS OF TREATMENT AT A CONVALESCENT CENTRE

BY

H. STUART BARBER, M.D., F.R.C.P.I.

ne Wing Commander; Officer in Charge of a Medical Division

A comparatively recent survey of the trends in the incidence of rheumatic fever Glover (1943) presented figures showing a remarkable decline in the disease since the beginning of the century, to the extent of inducing him to refer to it as an "obsolescent" disease. Nevertheless, in large communities of young adults such as are to be found under conditions of military service rheumatic fever still provides a problem of some magnitude. Before the late war the frequency of the disease among the boys and youths in the training establishments of the Royal Navy and in the apprentice schools of the Royal Air Force had been a matter of concern to the respective medical directorates. In the Air Force the boys enter the apprentice schools at the age of 15 to 16 years, to undergo an expensive course of training lasting three years. Applications to enter the schools have always exceeded the number of vacancies, and the boys are selected by a competitive examination. In consequence of rheumatic fever not only was there a steady and persistent loss of potential craftsmen upon whom a considerable amount of public money had been spent, but in many cases a promising career was ruined. While a certain wastage was to be expected, it was felt that if these cases could be given the necessarily protracted convalescence under Air Force auspices a high proportion might again become fit for service. Shortly after the outbreak of war it was therefore proposed to establish a convalescent centre for cases of rheumatic fever, and early in 1940 some twenty beds were set aside for this purpose in one of the Royal Air Force general hospitals. To ensure that only those cases which would benefit from such treatment were admitted, all patients had to be recommended for transfer by one of the Air Force consultants in medicine. A few acute cases were admitted direct from neighbouring units served by the hospital. It was soon found necessary to increase the number of beds at the centre, as, in addition to the apprentices, convalescent cases from among the regular Air Force personnel came to be included. Towards the close of 1940 it was decided to move the centre to another hospital, where it continued for a further nine months. Both because of a greater number of beds and because the demands upon the consultants in medicine did not permit of their making individual recommendations, patients suffering from various forms of chronic rheumatism were also treated.

The principal consideration in the treatment was an adequate period of rest followed by a graduated return to activity as the condition, gauged by the temperature, pulse rate, and the erythrocyte sedimentation rate, showed improvement. The sedentation rate was taken at weekly intervals, and when there was a doubt regarding the size and configuration of the heart this was checked radiologically. An electrocardiograph was not available for use in all R.A.F. hospitals in the early years of the war, and it was not possible to make serial tracings. As soon as the rate of progress permitted, occupational therapy was encouraged. No complications were encountered, and, despite occasional retrogression after infections of the upper respiratory tract, no true relapses occurred.

The system of medical records in the Air Force makes a follow-up of such patients a relatively easy matter. In 1945, four years after the centre had closed, in view of the interest concerning the ultimate progress of these cases and to make some assessment of the value of the centre, such a follow-up was initiated. Sixty-five airmen convalescent from acute rheumatic fever had been treated. The majority were in their teens, and the average period of detention in hospital was 149 days. Of the original number admitted it was considered advisable to invalid eight out of the Service, of whom four had developed mitral stenosis and four aortic incompetence. The remaining 57 were retained in the Service, but owing to errors in numbers or names it was found possible to trace only 48 of these. At the time of their return to duty 28 showed signs of minor cardiac involvement by soft apical or basal systolic murmurs.

The remainder appeared to be fully recovered. On returning to duty all were lowered in medical category, and were subject to three-monthly examination by a medical specialist until they were considered fit to return to a full category. When the medical documents were seen in 1945 it was found that out of 48 men 34 had been recategorized to Grade 1, and of these two had been accepted for air-crew duties, in which the physical standards are extremely high. Ten men had been retained in Grade 3, and four had been invalided out of the Service—two on account of mitral stenosis and two because of aortic incompetence. The after-history of these men disclosed little of interest, with one exception. Four patients developed symptoms of a psychoneurotic nature and were noted at later examinations to have a nervous tachycardia or effort syndrome. An incidence of from 6 to 8% showing such symptoms seems unduly high, and gives rise to some doubt regarding the wisdom of frequent examinations. A similar state of affairs was observed in some of another group of patients coming for three-monthly review of their chests because of the finding of opacities of doubtful significance on mass radiography. In suspected phthisis, and after diseases like rheumatic fever, it is a difficult matter to strike a nice balance between adequate observation and the liability of inducing a neurosis by too much attention to the chest or heart. In defence it may be argued that the seed flourishes only in fertile ground, that at a later date the psychoneurosis would have manifested itself in other ways for other reasons, and that the advantages of adequate after-care outweigh such possible complications. In this connexion it is of interest to refer to a study made on the cases of chronic "rheumatism" admitted to the centre in the later stages (Flind and Barber, 1945). It was found that a high percentage were suffering from one or another of the common neuroses and had shown a clear predisposition to neurosis from an early age. In an attempt to obtain a control group a psychiatric assessment was also made on some of the convalescent rheumatic fever patients. Unfortunately the decision to terminate the rheumatic centre, and a marked decrease in the number of these patients, made this group from a statistical point of view valueless, but in the 15 patients studied no evidence of a psychoneurosis was found. The only other point of interest is the small number who had a further attack of rheumatic fever. Only two were again treated in hospital on this account.

The majority of observers are agreed that rheumatic fever is closely related to infections of the upper respiratory tract, in particular by the haemolytic streptococcus. How this association plays its part in the onset of the attack of rheumatic fever is not clear, but, despite the strictures of Aschoff (1935) regarding an allergic factor, there is a distinct tendency to view at least the joint manifestations as being of this nature. To some extent this hypothesis is supported by the occasional appearance of joint involvement similar in most respects to that of rheumatic fever in poliomyelitis (Poynton, 1943) and in tuberculosis (Sheldon, 1946). On the other hand, the heart lesions would seem to be due to a direct infection of the valves by the haemolytic streptococcus; for Green (1939), Collis (1939), and Thomson and Innes (1940) reported success in culturing these organisms from the heart valves in about half their necropsies on cases of rheumatic fever dying in the acute phase. The importance of infections of the upper respiratory tract was stressed by Bradley (1934), who considers that the precursor pharyngitis is an essential part of the rheumatic state, though it may be concealed under the guise of the common cold. In a later communication Bradley (1938) remarks that the spread of infection is intensified by the simultaneous presence or previous occurrence of other catarrhal diseases. Similarly, Green (1942) states that the increase of acute rheumatic fever in winter is due to the prevalence of respiratory infections and not to any climatic influence by itself. He suggests an enhanced virulence of the infecting organism as a result of passage through a community. Recently Glover (1946) has again emphasized this. At the appropriate season the carrier rate of one particular strain of streptococcus rises and is followed by an epidemic of acute tonsillitis and a little later by cases of acute rheumatism in the ratio of about one to every ten of acute tonsillitis. The question of susceptibility of certain classes of the population, particularly in the lower-income groups, is also thought to be of importance. Green (1942), in observations on epidemics in the training establishments of the

Royal Navy, noted a higher incidence among boys coming from Tyneside, at that time designated a "distressed area." Poynton (1938), however, remarks that the apparently higher incidence among the poorer classes compared with the well-to-do may be a matter of relative numbers, and that the percentage incidence is probably the same. This is not a view generally held, and Keith (1941) mentions the economic status as one of the fundamental causes, while Glover (1943) ascribes the wartime decrease of acute rheumatism to abundant employment and the greatly increased provision of school milk and meals for the children. It should be possible to elucidate this important point, though it is not unreasonable to suggest that overcrowding, poor hygiene, and inadequate diet will at least predispose to upper respiratory infections and, in susceptible individuals, to subsequent rheumatic fever. Under Service conditions, however, the hygiene and diet are of a high order, even if overcrowding takes place at times. In peacetime overcrowding did not take place in the R.A.F. apprentice schools, where spacing in the barracks was carefully controlled. In these centres the important factors would appear to be a community of young adults undergoing military training, with its stress on hardihood in all kinds of climatic conditions, plus a constant addition of new arrivals susceptible to strains of the infecting organism, against which the older members have gained an immunity.

At the time of the inception of the rheumatic centre the full importance of the precursive upper respiratory infection was not realized and consequently no inquiry into this was made. When the medical documents were examined in 1945 a note was made of any containing an entry for tonsillitis or nasopharyngitis. In 14 of the 48 cases traced there was recorded an admission to either the sick quarters or the hospital for an upper respiratory infection within four weeks before the onset of the rheumatic symptoms. Of these, four were diagnosed as tonsillitis and ten as nasopharyngitis. The interval between the two illnesses varied from five to eighteen days. The only entries recorded in the medical history are admissions to hospital exceeding 48 hours in duration, specialist reports, and medical boards. It can therefore be safely assumed that a certain proportion of the remainder also had milder infections in nature, for which they may have reported sick but were ill enough to require admission to hospital.

The incidence of rheumatic fever in the Royal Air Force as a whole in 1940 was 2.1 per 1,000, whereas among the boy entrants and apprentices it was 10.4 per 1,000 for the same period. In one epidemic in a Naval training establishment the attack rate was 63 per 1,000 (Green, 1942). It is therefore of paramount importance that adequate methods of prevention should be instituted. In the armed Forces of the United States one suggested solution was the rejection of all recruits giving a past history of rheumatic fever (Master, 1943, 1944; Holbrook, 1944). This measure would hardly suffice, for among the 65 patients treated in the R.A.F. rheumatic centre only two gave a past history of rheumatic fever, and in one of these that attack had occurred in the Service. The apprentices, too, are of an age when primary attacks may be expected. Tonsillectomy is regarded as being of no value (Keith, 1941), and Bradley (1932) goes so far as to describe it as a lost cause in the prevention of rheumatic fever. A way of preventing the precursive respiratory infections seemed a more hopeful alternative, and the sulphonamides offered a possible means to this end. Accordingly, at camps of the United States Army and Navy large-scale observations were made on the value of the prophylactic use of the sulphonamide compounds in the prevention of such infections and on the effect of the prevention on the incidence of rheumatic fever. The results came fully up to expectations. In the Army Air Force there was a reduction of 50 to 70% in the incidence of respiratory and streptococcal infections after the prophylactic administration of from 0.5 to 2 g. of sulphadiazine daily to each man (Holbrook, 1944). It was found that a reduction in the attack rate of acute rheumatic fever ran parallel with the reduction in respiratory diseases. A similar finding was reported by Coburn (1944) after the use of sulphonamides in the United States Navy. A small percentage of the men showed an idiosyncrasy to sulphonamides in prophylactic doses, but as the incidence was 1 in 10,000 it was concluded that the advantages far outweighed any risk entailed. There was no evidence either of

the development of sulphadiazine-resistant strains of bacteria or of mass sensitivity to the drug on the part of the subjects of the experiment. These findings suggest a promising form of defence against rheumatic fever, and might with advantage be given a trial in some of the British training centres. From the results obtained with the rheumatic centre it may be considered that it justified its existence, and that in the event of further outbreaks of rheumatic fever it might be revived.

Summary

A centre for convalescent cases of rheumatic fever in the Royal Air Force, and the results of treatment at the centre, are described.

The relationship between the upper respiratory tract infections and rheumatic fever, with a method of prophylaxis tried in the armed Forces of the United States, is discussed.

I wish to acknowledge the constant interest shown in the centre by the Royal Air Force Consultants in Medicine, Air Vice-Marshal A. F. Rook and Air Vice-Marshal J. J. Conybeare, and the assistance in tracing the patients after their discharge from the centre given by the Air Officer in Charge of Royal Air Force Records.

ERYTHROBLASTOSIS FOETALIS

BY

MARGARET VENTERS, M.B., Ch.B., M.R.C.O.G.,
M.M.S.A., L.M.

Erythroblastosis foetalis is not an exceedingly rare disease, but it appears to be uncommon enough to make the following cases worth recording.

Case Report

Mrs. E., aged 33, was first seen in December, 1944, when she was 23 weeks pregnant. This was her sixth pregnancy, and she had no living child. Her obstetric history was as follows:

First Pregnancy, 1934.—Full term. Normal confinement and delivery. Child died from pneumonia when 9 months old.

Second Pregnancy, 1936.—Full term. Normal confinement and delivery. Mother told that the child was jaundiced at birth; it died nine days later.

Third Pregnancy, 1937.—Patient had eclampsia. Child stillborn.

Fourth Pregnancy, 1940.—Patient admitted to hospital three weeks before term with oedema of feet, which subsided within 24 hours of admission. She was told that she had no rise of blood pressure and that her urine was normal, but she was kept in hospital in view of her previous history. Foetal movement ceased two weeks later for no apparent reason, and she was delivered at term of a stillborn macerated foetus.

Fifth Pregnancy, 1943.—Aborted at three months.

The patient was a healthy well-nourished woman; her Wassermann reaction was negative. It was thought most probable that her second child had died of erythroblastosis, but her blood was not tested for the Rh factor owing to some difficulty in getting the test done at that time. The antenatal period was uneventful. It was decided to induce labour at 38 weeks, or earlier if any signs of toxæmia developed, and with this in view she was given stilboestrol dipropionate daily from 36 weeks onwards. The patient went into labour on the morning of the day on which she was to have come into hospital for induction; and had a rapid, almost precipitate delivery. When the membranes ruptured it was noticed that the liquor was of a dirty brown colour. The child was slightly premature in appearance, weighed 6 lb. 6 oz. (2.9 kg.), and was slightly jaundiced, but his general condition was quite good. Six hours after delivery the jaundice was considerably deeper; the child was very fretful and did not appear to be at all well. As his condition was

thought to be partly due to the rapid delivery, he was given an injection of vitamin K and small doses of potassium bromide with chloral. The next day the child was deeply jaundiced, but he was no longer fretful and seemed much better. For the next two days there was very little change and he took his feeds well. After that the jaundice gradually grew less and by the tenth day it had completely gone, but he was very pale and lethargic, and took his feeds with difficulty. Two days later he started to improve, and was discharged when three weeks old, doing very well. When last seen at 8 months of age he was a normal healthy well-developed child. While in hospital he was partly breast- and partly bottle-fed, breast milk being given when it was available, the mother herself having practically none; by the time he left hospital he was being artificially fed. Small doses of iron (mist. ferri et ammon. cit.) were started on the twelfth day and gradually increased, and as soon as it could be obtained the child was given a dried-milk food containing extra iron, as this was easiest for the mother.

Both parents and the child were tested for the Rh factor when he was 6 months old, and the report was as follows: Father: Blood group O Rh-positive; genotype R₁R₁. Mother: Blood group O Rh-negative; the serum contained an "incomplete antibody" as described by Race and Taylor. Child: Blood group O Rh-positive; genotype R₁R₁. A note was added by the pathologist that these findings confirmed the clinical diagnosis of erythroblastosis foetalis.

Discussion

Erythroblastosis foetalis is a hereditary disease of the newborn, characterized by anaemia, severe jaundice evident at birth or appearing shortly afterwards, and oedema, with enlargement of liver and spleen, leucocytosis, and erythroblastosis. It is primarily an acute haemolytic anaemia (Damshek *et al.*, 1943), the other pathological changes being subsequent to the haemolytic process. The disease, however, may vary in intensity, the mildest cases being those in which anaemia alone is present, and the most severe those in which there is generalized oedema. The condition is due to immunization of the mother with some factor present in the foetal blood, and this in about 90% of the cases is the Rh factor, the father and child being Rh-positive and the mother Rh-negative. The theory of immunization of the mother by foetal erythrocytes, with the production of antibodies which subsequently cause intra-uterine haemolysis of the foetal blood, was first suggested by Otteoburg in 1923, and in 1940 Landsteiner and Wiener first demonstrated the Rh agglutinin in the red cells of about 85% of the people tested. This figure has been confirmed by Cappell (1944) and Plaut, Barrow, and Abbott (1945). Levine, Katzin, and Burnham in 1940 found an atypical agglutinin in the serum of several patients who had given birth to infants suffering from erythroblastosis, and these antibodies corresponded in activity to the anti-Rh agglutinins produced by Landsteiner and Wiener in animals. The Rh factor, which depends upon a complex of antigens borne in the red cells, is inherited as a simple Mendelian dominant (Landsteiner and Wiener), and the theory of the mode of production is as follows.

The Rh-positive father transmits the Rh factor to the foetus. The Rh antigen of the foetus passes through the placenta into the mother's circulation. Her blood, which is Rh-negative, reacts to the antigen by building up antibodies against it—the anti-Rh agglutinins. These in their turn pass through the placenta into the foetal circulation and there agglutinate the Rh-positive cells. Haemolysis of the foetal blood and haemolytic changes ensue, followed by other pathological changes, the most important of these being damage of the liver parenchyma. In about 10% of the cases the immunizing agent is not the Rh factor, and in some of those cases the disease is thought to be due to immunization of a group O mother by the group A or B blood factor. Six such cases are reported by Polayes (1945). The disease does not usually develop with a first pregnancy, but as a rule shows itself in a second or in later pregnancies, the theory being that it may take more than one pregnancy to develop sufficient antibodies in the mother's blood to act on the foetal blood.

It has been shown that mothers of infants with erythroblastosis show a high incidence of abortions, miscarriages, stillbirths, and toxæmias (Levine *et al.*, 1941; Polayes, 1945). The main disease concerned in the differential diagnosis is congenital syphilis, in which the clinical findings may be almost identical. The other diseases that have to be excluded are antenatal infection, post-natal infection, congenital malformation of the bile ducts, haemorrhagic disease of the newborn, congenital heart disease, and icterus neonatorum. The previous history

(if any), the clinical findings, and the presence of anti-Rh agglutinins in the blood of a Rh-negative mother make the diagnosis as a rule fairly easy, but difficulties do arise. Occasional mild cases may be missed either through not being observed or through being wrongly diagnosed. Also, the finding of anti-Rh agglutinins in the blood of a Rh-negative mother, though almost pathognomonic of the disease, is not absolutely so, as cases have been observed in which the anti-Rh agglutinins were found in the blood of the mother but the child was normal. Again, the absence of anti-Rh agglutinins does not exclude the disease. As stated before, about 10% of the cases reported are not due to immunization of the mother by the Rh factor; and in other cases, though the mother may be Rh-negative, no anti-Rh agglutinins may be found. Davidsohn (1945) states that the best time to test for the anti-Rh agglutinins is not immediately after delivery but about ten days later. Race and Taylor (1944) have described a method by which an "incomplete antibody" can be found in some cases in which the mother is Rh-negative and erythroblastosis is suspected but in which no antibody can be detected by ordinary means. The anti-Rh agglutinins may be found in the blood of the mother up to two years after delivery. It is interesting to note that the disease does not necessarily become more severe with each succeeding pregnancy, but may vary in intensity; and Davidsohn (1945) points out that there is some evidence to show that no direct relation exists between the antibodies in the mothers' blood and the severity of the disease in the baby.

The only efficient treatment in severe cases is blood transfusion, and it has been found that transfusion with Rh-negative blood is more effective than transfusion with Rh-positive blood, possibly because the Rh-positive blood of the infant is undergoing destruction (Levine *et al.*, 1941).

ACHROMOTRICHIA IN TROPICAL MALNUTRITION

BY

WILLIAM HUGHES, M.D., M.R.C.P.
(Colonial Medical Service)

Depigmentation of the skin is one of the most striking results of malnutrition as it is seen in young Africans. This phenomenon has fixed the attention of native as well as European (Williams, 1933; Gillan, 1934; Trolli, 1938; Trowell, 1941) observers, and many of the names under which the prevailing syndrome of malnutrition has been described—kwashiorkor, cheveux blancs, etc.—signify depigmentation of the skin or its appendages. From what we now know of the diet consumed by the patients and the response to treatment we can refer the depigmentation to deficiency of one or more members of the Vitamin B₂ complex. Carrying the analysis a little further, I have tried to show (Hughes, 1946) that kwashiorkor—the most widely prevalent syndrome of deficiency with depigmentation—is associated primarily with a deficiency of riboflavin. There are, however, certain cases of depigmentation in which achromotrichia is a most striking feature while the clinical signs of arbofavinosis are minimal or absent.

In a study of malnutrition in Lagos during the past four years I found the incidence of achromotrichia widespread, and the first impression was that it was constantly associated with depigmentation of the skin. Further investigation, however, revealed: (1) In acute recent cases of kwashiorkor

depigmentation of the skin may be intense while the hair still retains its colour. Alopecia of a "moth-eaten" type is constant. (ii) In chronic cases of kwashiorkor, achromotrichia and alopecia run parallel with depigmentation of the skin. (iii) Among the remaining cases, which constitute a large group, we identified eleven cases of what appears to be a separate syndrome in which achromotrichia is the most prominent feature. In these cases the moth-eaten alopecia of kwashiorkor was not seen, signs of ariboflavinosis were minimal or absent, and, furthermore, the mechanism of depigmentation appeared to be different from that which operates in kwashiorkor.

To appreciate the difference between kwashiorkor and the syndrome of nutritional achromotrichia, about to be described, it will be necessary to recount briefly the main epithelial changes of the former, with particular emphasis on the pigmentary changes which can be ascribed to ariboflavinosis.

Depigmentation in Kwashiorkor

The symptomatology and lesions of kwashiorkor have been described by the authors to whose work reference has been made above. The epithelial changes fall into two groups:

(a) *Those Associated with Ariboflavinosis as seen in the Adult.*—

(1) *Glossitis*.—The superficial epithelium is shed, revealing a pink or magenta tongue, without fissuring and without great enlargement of the papillae. (2) *Desquamation* about the lips, angles of the mouth, naso-labial sulci, eyes and ears, and external genitals. The rash consists of *hyperpigmented scales on a hypopigmented background*. Compared with the adult ariboflavinotic syndrome the exfoliation is more extensive. The rash extends from the oral lesions on to the face and neck and from the perineal lesions on to the thighs, buttocks, and abdomen and is more intensive; and fissures and erosions are common, especially about the mouth, flexures, and perineum.

(b) *Desquamation and Alopecia not seen in Adult Ariboflavinosis.*—(1) There is intense exfoliation on the dorsa of the hands and feet, and the rash may extend up to the shoulders and thighs respectively. (2) In recent acute cases the hair is loose and can be drawn out painlessly in large bunches. At this stage, however, it should be noted that the colour is still a normal dark brown and texture coarse. In chronic cases the hair comes up fine, straight, and sparse.

stologically, the changes everywhere are those of paratosis. In the skin there is a thinning out of the epidermis, and nucleated cells containing pigment can be seen in the stratum corneum, which is partly detached. Sections of the scalp reveal, in addition, large oval spaces lined with epithelium, indicating the sites from which the superficial row of hairs have been shed. It is reasonable to assume that the process of hyperkeratosis accounts for the alopecia and depigmentation, the continual loss of cells and pigment creating demands which the normal resources of the epithelium cannot supply.

Primary Nutritional Achromotrichia

In the syndrome about to be described the most striking finding is achromotrichia. The clinical picture abstracted from eleven cases might be set down as follows.

The patients were of either sex—seven females, four males—between the ages of 4 and 10 years. The environment and previous history were similar to those which obtain in kwashiorkor. There was a history of diarrhoea in nine cases, in one of which *E. histolytica* was isolated from the stools. Malaria parasites—all *P. falciparum*—were found in routine slides in nine cases, but, as treatment was given only when indicated by fever, it was shown that recovery could occur in spite of this infection. Similarly, hookworm and roundworm infections, although heavy in some instances, were shown not to be the deciding aetiological factors. No exact quantitative studies have yet been made on the diet consumed by this type of patient. Qualitatively, cassava is the staple, but small quantities of cereals—rice, maize, and wheat flour—are also taken. Many ingredients, including green leaves, peppers, and variable amounts of fermented foods, go into the "soup." Of the more important ingredients—meat and fish—probably less than 1½ oz. (14 g.) daily reaches any one child. Milk is scarce, and is rarely consumed outside the large towns.

The hair is lightly pigmented, the colour ranging from white or light yellow to grey. The eyelashes are more pigmented than the scalp hairs, and appear yellow to reddish brown.

On the scalp the individual hairs are straight or wavy—not curly as in the normal negro child. They are finer in texture than normal, but they are firmly embedded in the scalp and cannot be drawn out painlessly as in kwashiorkor. Hence in typical cases there is no alopecia.

The skin is generally hypopigmented; it showed some powdery desquamation in all cases, although this was only slight and localized in some. Infestation with ectoparasites—scabies and chiggers—is unusually intense. "Septic spots," scabs, and erosions are common, but they clear up as soon as the ectoparasites have been dealt with.

The affected children are unusually docile or even apathetic, and this may partly account for the high infestation with ectoparasites. The behaviour and appearance are so "feminine" that in male cases it is often difficult to believe the patient is a boy.

All cases showed anaemia. Oedema was noted in every case, but it was never gross as in kwashiorkor. Muscular wasting was slight or absent. Among other signs we observed an unusually heavy deposit of "tartar" on the teeth, with patchy gingivitis. The teeth were small, and in one case the tips of the lower incisors were worn off, resembling the appearances often seen after middle age. During convalescence the teeth came up with the attached ring of "tartar," and the gums receded, leaving a clear white space between "tartar" and gum. An important negative finding was the absence of any active lesion of the ariboflavinotic syndrome. In one case there was depigmentation at the angles of the mouth and tip of the prepuce.

Microscopically, the individual hairs were seen to be yellow or reddish, straight or wavy, and more cylindrical than normal. Hairs removed during convalescence showed these appearances at the free ends, while below they were black, stout, and strap-like. In typical cases we noted at all stages that the hairs broke off when we tried to remove them for examination. This is in contrast with kwashiorkor, in which the hairs with most of the bulb attached come out with a gentle pull. Sections of skin were not available for histological study. Clinically the absence of hyperpigmented scaling which characterizes kwashiorkor suggests that loss of pigment through exfoliation is not sufficient to account for the extensive depigmentation.

The natural course of the condition is unknown. Probably most of these patients drift into a state of chronic marasmus or die from sepsis or concurrent disease. When put on a diet containing liver, milk, and yeast changes occur rapidly. The hair darkens near the scalp and comes up strong, dark, and curly. The minimum time taken for the first change in colour to be observed was three weeks. The anaemia clears up, the oedema disappears, the child puts on weight and recovers its natural aggressiveness. On the hospital "full diet" for adults, one patient, aged 9 years, failed to put on weight or make any progress for four weeks.

We gave injections of 25 mg. of calcium pantothenate daily for two weeks to two cases, using the adult "full diet" as a basal ration. After three weeks the hair came up black near the scalp in both cases. A case on the same diet, with 100 mg. *p*-aminobenzoic acid thrice daily for two weeks, showed no change after a month. We know too little about the pantothenate content of local foods, and in these cases the controls were not strict enough to allow us to incriminate pantothenic acid definitely as the missing factor of the B_3 complex, but the results were suggestive.

The following case exemplifies the main features of the condition:

Illustrative Case

An African boy aged 4 years was admitted to the African Hospital, Lagos, on April 13, 1945, for general weakness, oedema, and cessation of growth. The parents, who lived in the country, placed the child in hospital and went away without giving a detailed history of the case.

On examination he showed generalized hypopigmentation, most pronounced about the scars of old scabietic lesions, which were still dead-white. The hair on the scalp was white, fine, wavy, and fairly luxuriant in growth. The individual hairs could not be extracted easily. The eyelashes were red. Scabies was generalized and intense. Six fully grown chiggers in addition to numerous smaller ones were removed from about the toes. There was pitting oedema

about the ankles and over the sacrum. The mucous membranes were pale, and a blood count on April 27 showed: R.B.C., 1.8 millions; Hb, 30%; W.B.C., 14,000 (polymorphs 39%, lymphocytes 3%, monocytes 2%, eosinophils 5%). The tongue, lips, and external itals were free from lesions. There was some "crazy-pavement" ing on the shins.

He was noticeably docile and feminine in appearance. Not only he not resent the extraction of occasional hairs for examination, even the giving of hypodermic injections provoked no resentment.

Treatment.—The patient was put on the basic children's diet, which contains 6 oz. (170 ml.) of milk daily. He was given daily injections of 40 mg. of calcium pantothenate for 12 days. The scabs were removed, and the scabies responded rapidly to benzyl zoate solution.

After three weeks there was a good deal of improvement in the general condition, although some oedema was still present. The rashes could be seen coming up dark near the scalp, and with a magnification of $\times 10$ quite a sharp line of demarcation could be made out in individual hairs. At this stage he was put on iron and cod liver oil, dewormed. Progress was rapid; his weight increased, and he became naughty and boyishly aggressive in about six weeks from admission. His weight on admission was 21 lb. (9.5 kg.), and on discharge (June 16), 23 lb. (12.7 kg.).

Discussion

The circumstances in which achromotrichia or grizzling hairs might be classified as follows:

1. In carnivora inhabiting the polar regions, where it occurs as a seasonal change. Genetic factors probably account for it here, although nutritional factors cannot be completely ruled out.

2. In middle and old age in man—*canities*. The process is common in negroes, although perhaps not so common as in white races. Sieve (1941) reported some improvement in cases treated with *p*-aminobenzoic acid, but his results have had no general confirmation.

3. Experimentally, grizzling and alopecia have been produced in various circumstances of malnutrition in animals, and particularly with deficiencies of the B₂ complex. Morgan and Simms (1940) produced grizzling in rats, which was cured by filtrate containing pantothenate. This was confirmed by Hanna *et al.* (1941), using pantothenic acid.

Ansbacher (1941) identified *p*-aminobenzoic acid as an anti-grey-hair factor in rats. Inositol deficiency, according to Woolley (1941), induces grizzling in mice. According to Hartin and Ansbacher (1941), inositol and *p*-aminobenzoic acid are complementary in the prevention of grizzling. Martin (1942) has reported grizzling in rats following a deficiency of folic acid. The grizzling which arises from pantothenate deficiency in rats is associated with other signs such as blood-tinged whiskers, "rusty spots," and, post mortem, adrenal haemorrhages. Signs of pantothenate deficiency in the pig include an extensive dermatitis, ulcerative colitis, and spastic paralysis.

Kerlan and Herwick (1943) have reported negative results with calcium pantothenate, in a dosage of 20 mg. orally per day for six months, in the greying (canities) of middle and old age in man. The grizzling in our cases has been observed only in children and young adults, and responds to dietetic treatment. We are satisfied that the deficiencies concerned in both types of achromotrichia can be traced to factors of the B₂ complex. Our efforts at a more detailed analysis of the aetiology have led us to the following conclusions:

(a) The parakeratosis of recent acute kwashiorkor, by giving rise to rapid and extensive exfoliation, leaves a depigmented skin at the site of exfoliation. The normal dark curly hairs fall out and the new crop is sparse and depigmented. The missing factor is riboflavin.

(b) In primary nutritional achromotrichia there is a deficiency of some factor of the B₂ complex in the diet. This factor controls the colour and texture of the hair and may have some influence on haemopoiesis and the development of the teeth. The missing factor may be pantothenic acid.

(c) There is a large group of mixed cases in which both riboflavin and pantothenate deficiencies operate. It is possible that in many cases of kwashiorkor, riboflavin deficiency, by causing anorexia and inanition, would lead to a secondary deficiency of the B₂ factor concerned with pigment formation.

Summary

Two types of achromotrichia have been encountered in malnutrition associated with deficiencies of the vitamin B₂ complex in Africans.

One, associated with alopecia, is seen in kwashiorkor. Parakeratosis appears to be responsible for this type.

The second type—primary nutritional achromotrichia—is believed to be due to a deficiency of a B₂ factor—possibly pantothenate—in the local diet.

I am indebted to the pathologist, African Hospital, Lagos, for the sections of skin in kwashiorkor and for the other pathological examinations; and also to the Medical Adviser, Colonial Office, for permission to publish this paper. Messrs. Glaxo Laboratories, Ltd., kindly provided free supplies of calcium pantothenate.

THE CONUS MEDULLARIS SYNDROME IN SPINAL CONTUSION

BY

G. A. RANSOME, M.R.C.P.
Lieut.-Col., I.A.M.C.

R. K. A. van SOMEREN, F.R.C.S.Ed.
Lieut.-Col., R.A.M.C.

AND

J. F. STOKES, M.R.C.P.
Lieut.-Col., R.A.M.C.

The conus medullaris syndrome is an uncommon variant of the clinical picture of spinal concussion or contusion. Its rarity has prompted us to give a brief description of two cases. The first case is recorded from memory; this patient was studied in Singapore by one of us (G. A. R.) in conjunction with Col. Julian Taylor, and his case sheets shared the fate of many others in the Malayan debacle. The second case was observed on Ramree Island.

Case Records

Case 1.—A young aircraftman was sleeping in his quarters on the night of Dec. 10, 1941, when a sudden explosion blew him through an asbestos partition on to the floor beyond. Though he was painfully aware of a bruise on his right hip he could move his legs, and asserted that he could have walked to the C.C.S., to which he was carried on a stretcher. With the aid of morphine he slept till the following morning, when he awoke to find himself unable to pass water and incontinent of faeces. He was first seen by G. A. R. on Dec. 19. There was complete anaesthesia to all forms of sensation on both sides of S₃, S₄, and S₅. An extension from the anaesthetic area of hypo-aesthesia for a few inches down the back of each thigh argued partial involvement of S₂. Power in the lower limbs was good, apart from some weakness of the flexor thrust in the right foot and weakness of the long flexors of the digits in both feet. There was no loss of vibration sense. The knee-jerks were present, the ankle-jerks absent. Lumbar puncture showed no increase of cells, protein, or pigment. Skiagrams of the whole spine revealed no fracture. Cystometry showed an atonic bladder. There was little improvement by the time he left Singapore on Feb. 10, 1942. The hypo-aesthetic area (S₂) had receded, but there was no change or dissociation in the main area of anaesthesia. The flexor thrust of the right foot was somewhat stronger. Some form of softening of the conus was postulated. Ignorance of the precise pathology involved made prognosis difficult, but it was considered poor in view of the minimal change in eight weeks.

Case 2.—No other case was reported in the Far Eastern theatre of war until May 29, 1945, when a young sepoy of the Indian Engineers fell from a tree, first on his feet and then on to his back. He was carried to his tent complaining of pain over the lower thoracic spine. He could flex his legs, but made no attempt

stand: His unit M.O. reported normal power and movement of the limbs, but had to catheterize him for retention of urine. Examination on May 29 showed a symmetrical area of anaesthesia involving S3, S4, and S5, with partial affection of S2, though maximal stimuli were felt over the latter area. There was no dissociated anaesthesia. Abdominal and cremasteric reflexes were present.

May 29, 1945.

July 22, 1945

Diagrams showing anaesthetic and hypo-aesthetic areas in Case 2. Stippled area=anaesthetic; black area=hypo-aesthetic.

Knee-jerks were present, ankle-jerks absent, and plantar responses flexor. Lumbar puncture revealed clear fluid under a pressure of 135 mm. C.S.F. There was no block or any increase in cells, protein, or pigment. Skiagrams showed no fracture of the spine. Cystometry was not carried out. On May 29 suprapubic cystotomy was performed. By June 4 the hypo-aesthetic area of S2 had largely disappeared, and there was no dissociation. On June 9 sensation began to return in the anaesthetic area, and the anal sphincter was functioning. On July 22 muscular tone was normal; no loss of power was detected. Knee-jerks were present, ankle-jerks absent, and plantar responses flexor. Bulbocavernosus and anal reflexes were negative. Erection was absent. Sensation: Cotton-wool touch well appreciated over all areas except immediately around the anus. Sensitivity to pinprick all over S2, S3, and S4, but well-defined hypo-aesthesia over this area. Loss of sensation over the immediate perianal region. Hot and cold sensation poorly appreciated over S2, S3, and S4, covering an area slightly more extensive than that hypo-aesthetic to pinprick. Protopathic heat appreciated over this area. There was blunting of pinprick sensation and poor appreciation of heat over the sacral areas of the scrotum and penis, with a clear-cut change to normal when the lumbar areas were reached. Urine had yet passed per vias naturales. Since war moves doctors d patients back, it was improbable at the time of writing that an could be followed much further, but it will be seen from agram that there has been considerable improvement over a of time comparable to that during which the first case was rved.

Discussion

It only remains to call attention to the fact that, as the anaesthesia resolves in Case 2, its dissociation, not apparent during the first few weeks of recovery, is reminiscent of the sensory loss seen in cases of syringomyelia. This suggests to us that the essential morbid anatomy consists of a haemorrhage into the grey matter of the conus medullaris.

Medical Memoranda

Perforated Duodenal Ulcer at the Age of 12

The following case is of interest in view of the age of the patient and the absence of any previous dyspeptic symptoms.

CASE HISTORY

The patient, a girl aged 12, was admitted to hospital on Nov. 15 complaining of severe generalized abdominal pain of two hours' duration accompanied by repeated vomiting and nausea. There were no urinary symptoms and the child had had a normal motion that morning.

On examination she was obviously suffering from a moderate degree of shock. The tongue was slightly coated and there was generalized tenderness, maximal just below and to the left of the umbilicus, with marked guarding in all quadrants. There was no abdominal hyperaesthesia, and on rectal examination she was tender on the left side, both anteriorly and posteriorly. The patient was treated for shock, and after four hours was considered fit for operation.

The abdomen was opened through a right paramedian incision and yellowish-brown fluid was found in the lower peritoneal cavity. Perforation of the anterior wall of duodenum 1/16 in. in diameter was discovered from which bile-stained fluid

was oozing. Induration around the perforation suggested the presence of a duodenal ulcer. The wound was sutured in two layers and closed with suprapubic drainage.

The child made an uninterrupted recovery, and was given six weeks' in-patient medical treatment, including dieting, antispasmodics, antacids, before discharge. No dyspeptic symptoms were complained of before or after the operation.

My thanks are due to Dr. R. R. M. Porter, senior honorary surgeon to the Southport Infirmary, who performed the operation, for permission to publish this case.

K. B. N. FREEMAN, M.B., Ch.B.
Senior House-Surgeon,
Southport General Infirmary.

Technique for Use in the Guillotine Operation

The guillotine operation in recent years has largely fallen into disfavour among E.N.T. surgeons for the very good reason that while it was possible to be certain of a full view unobscured by blood in attacking the first tonsil, the operator's success in dealing with the second was often rendered extremely difficult—not to say impossible—by haemorrhage filling the pharynx from the bed of the first tonsil. A technique which I have followed for some considerable period eliminates this difficulty.

It is, of course, a truism that each case must be examined to make certain that the tonsil is of the infantile pedunculate type and not of the adult type in which the lower pole blends insensibly with the lymphoid tissue on the lateral pharyngeal wall and the back of the tongue. In the latter case it is impossible to engage the guillotine, and the method should be dissection. In cases suitable for the guillotine operation, which in my opinion form the great majority of infantile cases, the following technique is adopted.

METHOD

The patient is premedicated with "seconal" (dosage appropriate for age and weight) and 1/100 gr. (0.65 mg.) of atropine by mouth one hour before operation. Premedication carried out in this way entirely eliminates psychological trauma, and there is, in fact, no need for the child to know that an operation has taken place, as a skilled anaesthetist can induce without the patient realizing what is happening. Induction is by ethyl chloride followed by open ether, anaesthesia being carried to the top of the first plane of the third stage.

A tonsil gag is inserted and a final view of the field taken by means of a right-angled spatula. The surgeon then has available two matched guillotines of suitable size. It is essential for the success of this technique that the guillotines used should be so blunt that there is no fear of their cutting through the tissues when they are closed; the tonsils are thus completely snared, and are removed by digital dissection with the first finger of the left hand pressing the lateral pharyngeal wall away from the tonsil, and not by tearing the tonsil off the lateral pharyngeal wall by traction with the guillotine. Having selected the size required, he then stands at the head of the table, the anaesthetist steadying the head while standing to the left, and at the same time controlling the gag. The operator engages the guillotine on the left tonsil, closes it, the handle then being handed to an assistant, who presses the guillotine as much to the left as is possible. The surgeon then takes the other guillotine, changes his position to the right-hand side of the patient, and proceeds to guillotine the right tonsil in the usual way, removing it completely. His assistant then hands to him the first guillotine, which is engaged on the left tonsil, and he then proceeds to complete its enucleation. By this time the patient should be coming round from the anaesthetic, and the adenoids are then removed.

In my experience this makes the operation extremely easy; there is no hurry or rush to attack the second tonsil, and it is surprising, but true, that there is plenty of room in even a very young child's mouth for two guillotines to be *in situ* together. The teaching of the operation to a house-surgeon is also much easier, as the surgeon himself has entire control of the situation during the operation, which is, of course, impossible by the usual technique, because if the learner has failed with the second tonsil the mouth is then a pool of blood, the patient is coming round from the anaesthetic, and it is practically impossible for the surgeon to correct the mistake made by the operator. I now carry out this technique exclusively. In my hands I find that the disadvantages of the guillotine operation are eliminated. One can by this method be as certain of removing both tonsils completely as one is when carrying out the dissection operation.

MARTIN HENRY, M.R.C.S., L.D.S.,
Aural Surgeon, Chelmsford and Essex Hospital.

Reviews

NEUROPATHOLOGY

Textbook of Neuropathology. By Arthur Weil, M.D. Second edition. (Pp. 356; 289 illustrations. 25s.) London: William Heinemann Medical Books.

It is ten years since Dr. Arthur Weil's text appeared, and partly because of its intrinsic merits, and partly also because it came at a time when such a book was badly needed, it became very popular. The second edition is very similar to the first, and it remains a fairly small textbook of neuropathology which deals with fundamentals. Dr. Weil has, however, recognized the rapid progress of experimental neuropathology in some of the additions he has made in this edition. The more welcome of these are short sections dealing with the vitamin deficiency diseases and the pathology of different forms of shock treatment of the psychoses. The text is unusually well illustrated, for there are nearly as many illustrations—mostly photographs—as there are pages, but we have become so used to excellent reproduction of photomicrographs that we feel that Dr. Weil could have been better served in this respect. Nuclear and cellular detail is often blurred, and some of the plates will not mean much to any but the expert who knows what to read into a picture.

An appendix of staining methods contains formulae for ten stains, one chosen for each tissue, but this is such an important part of practical neuropathology that the book's value would have been increased if more than eight pages had been devoted to it. The book ends with a short bibliography with subject headings which at least gives an entry to the literature.

In assessing its value to the specialized student the price of the book must be added to its other qualities.

GENERAL SURGERY

The 1945 Year Book of General Surgery. Edited by Everts A. Graham, M.D. (Pp. 736; illustrated. 18s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

The 1945 volume of the *Year Book of General Surgery* maintains the high standard of selection which we have noted in previous issues; the editorship remains in the competent hands of Everts Graham. As might be expected, the number of articles on purely military surgery is smaller than in recent years, though there are still references to such subjects as parachute and fatigue fractures, blast injuries, gunshot wounds of the chest, immersion foot, etc. A book of this character obviously does not lend itself to a critical review since it consists wholly of summaries of large numbers of articles. The "Quiz" which the publishers continue to print on the cover sheet as an inducement to the ignorant to buy is always intriguing. We will quote some of the questions. "For what anatomical structure does one use the Lantounis periosteocapsuloplasty for congenital dorsal subluxation?" "Give the synonym for meningo-rachidian venous system and name the other three venous systems." "What is the relationship roentgenographically between a hamartoma and a Ghon tubercle?" And so on. If one's knowledge does not extend to the answers to these questions it is, of course, necessary to acquire the book.

HOSPITAL LAW

Notes on Points of Law Affecting Voluntary Hospitals. Second Edition. By Sir William Baynes, Barrister-at-Law. (Pp. 185. 10s. 6d.) London: British Hospitals Association. 1946.

This valuable little book is now considerably larger and includes a number of model forms. It makes no claim to be a textbook of hospital law, but consists of a number of sections, arranged in alphabetical order, dealing with the law relating to most of the topics within the province of a hospital administrator. It is built on the answers given by Sir William Baynes during the last fifteen years to questions actually put by secretaries of voluntary hospitals about their legal problems. He surveys, of course, the important decision of the Court of Appeal in *Gold v. Essex C.C.* (1942) 2 KB 293, in which a county council was held liable for the negligence of a radio-grapher and the court indicated clearly that the principles on which they had come to their decision would apply also to nurses. Perhaps he ought to have hinted, in saying that a

hospital is not liable for the negligence of its medical staff in purely professional matters, that the *Gold* decision threw some doubt even on this immunity, which the case of *Hillyer v. St. Bartholomew's Hospital* (1909) 2 KB 820 had been assumed to secure absolutely. The variety of the questions which he covers is astonishing. The hospital secretary will find information on such diverse subjects as the ownership of x-ray films, the circumstances in which a hospital may establish pay-beds, road traffic cases, trusts, insurance, employees, blood transfusions, suicide, and taxation. The book, however, does not cover questions peculiar to municipal hospitals or mental hospitals.

ESSENTIAL HYPERTENSION

An Introduction to Essential Hypertension. By Richard F. Herndon. (Pp. 88; illustrated. £2.50 post paid, or 14s.) Springfield: Charles C. Thomas; London: Baillière, Tindall and Cox. 1946.

This book by Dr. Richard F. Herndon contains more than its name implies. It comprises a very full survey of the whole topic, compressed into a remarkably small compass. But this does not make it in the least unreadable. It is, in fact, extremely interesting and well put together. The exposition is clear and complete. So much has been written on this subject lately, particularly in America, and so much important work has been done in the last ten or twelve years, that a full survey of these interesting and important advances is most valuable. As the references are given at the foot of the page, it is easy to turn to them as one reads. By using a variety of type, the important statements are made conspicuous. Hypertension is defined as existing when the pressures are consistently above 150/90. The aetiology and mechanism are clearly discussed, with a full exposition of the humoral factors, though the conclusion is that the real fundamental cause is as yet unknown. Looked upon from the physiological point of view, increased peripheral resistance provides the mechanism. The persistently raised pressure leads to pathological changes. That these changes in the kidney institute a vicious circle of progressive hypertension is hardly stressed enough.

The clinical aspects are divided into five stages; they are roughly similar to the grouping by retinal changes. In prognosis the importance of arteriolar changes and the presence of atherosclerosis and cardiac inefficiency are stressed, rather than the height of the blood pressure. Family history is hardly considered enough. The chapter on diagnosis discusses all types of hypertension; here the author is rather confused. The chapter on treatment comprises regime, diet, psychotherapy, drugs, and surgery; it is full of sound common sense and practical wisdom. There are a number of good illustrations.

This is an excellent little book, and well worth reading by anyone who wishes for up-to-date information on a subject which may well provide one of the next great advances in medical knowledge.

Notes on Books

A Food Plan for India is the title of a pamphlet issued under the auspices of the Royal Institute of International Affairs and published by the Oxford University Press at 3s. 6d. This anonymous study of the vital problem of India's food supply is introduced in a foreword by Prof. A. V. Hill. It was made by a private group of authorities, and derived directly from Prof. Hill's analysis of the situation after his five months' visit to India in 1943-4 at the invitation of the Government to advise on scientific matters, particularly in connexion with plans for future development. The pamphlet is the outcome of their investigations and discussions, in which they have drawn on the experience of many experts, both Indian and British, who have intimate knowledge of agricultural matters in India. Their plan outlines concrete proposals by which the extra 14 million annual tons of food can be obtained which, with a 50 million increase in population and with rising standards, will be required by 1953. Prof. Hill declares that, whether this is the best scheme or not, something essentially similar to it in form, scope, and boldness is the only way of meeting the food difficulty in the next ten years and of providing a foundation on which measures of longer range can be built. In this opinion he is supported by Sir Frank Engledow, professor of agriculture in the University of Cambridge.

MISS LOIS OAKES, with help from Prof. T. B. DAVIES, has produced a ninth edition of the little book *A New Dictionary for Nurses* which has had continuous popularity since its first appearance in 1932. E. and S. Livingstone, of 16, Teviot Place, Edinburgh, publish it at 4s., plus 3d. postage.

Preparations and Appliances

AN IMPROVED CLOSED CIRCUIT

Dr. E. F. GLEADOW, D.A., writes from Worcester:

"Pluto" came into being with the invasion of Europe, when delivery dates were a myth and the need for an additional closed circuit a reality, and during the very busy period that followed unflinching satisfactory service was given. No particular claim to merit can be made for this improvised closed circuit, but brief details of its construction may still be of interest to others, even though the time be past when anaesthetists were so often reduced to makeshift. That it came into being at all is due not so much to individual ingenuity as to the fortunate accumulation in the department of a number of spare parts, bits and pieces.

This collection was topped off by the chance arrival for the Boyle-Waters apparatus of a spare soda-lime canister without the essential flange, which naturally led to the immediate construction of the closed circuit itself; a couple of standard gas unions providing excellent connexions, readily detachable but unflinchingly gas tight.

Description of Apparatus

The Circuit.—The one-way valves have always been located in the E-piece carrying the mask and are of the rubber flap type used on the Alpha-Blease apparatus; the gases from the flowmeter are led direct to this point. The expiratory tubing terminates at the rebreathing bag on a standard Boyle mount plugged into the original "head" of the machine, which consisted of two more rebreathing bag-mounts soldered at right angles, the left vertical and the right horizontal. The arrangement of the latter is unchanged, but the apparent position of the former has been altered by the insertion of some copper tubing to facilitate the simultaneous control of the mount shut-offs by the addition of the large inverted U lever. In its original position the vertical mount had its bag aperture soldered to the free limb of the canister mount, and its lower leg connected by corrugated tubing to the absorber bottom,

FIG. 1

while the upper carried the escape valve and facepiece mount whence the inspiratory tubing leads. In either arrangement when one mount is shut off the other is open, and there is complete control of the circuit. This canister cannot be removed without opening the absorber. This is a fault found on at least one more professional apparatus. In its original form most of the tubing was

not detachable, but gradually tubing-mounts, angle-pieces, adaptors have eliminated this inconvenience.

The Flowmeter.—In the absence of a suitable flowmeter it was found possible to use the standard dry Coxeter, but, the rates of flow being such that the bobbins no more than trembled on their seatings, it was felt that some modification was essential before the machine could be left to comparatively inexpert supervision. W.

FIG. 2

depression was chosen as the best method, and was provided with the removal of all the original interior of the meter and the substitution of three plain glass tubes. To their tops the incoming gas was brought from the apertures in the flowmeter base by fine copper tubing, which can be seen as a dark shadow on the left of Fig. 2. A carburettor jet let into the top of each tube provided the necessary outflow, and was easily reamed out with a dental broach to give the optimum aperture. The outer casing was then filled with water to within an inch of the top.

Calibration was checked against three rotameters and carried out by collection under water against time; being recorded on the outside of the meter, it is necessary for the eye to be at the same level as the top of the depressed column to get an accurate reading, particularly since the convex glass and contained water form a magnifying lens for the tubes. The rates of flow obtainable are comparatively small, but have proved quite adequate where a bubble rate induction is employed. Induction with cyclopropane also would probably be easier with the substitution of a larger rebreathing bag. Stops have been fitted to the control knobs to prevent the passage of large volumes of gas through the depression tube. By-passes for oxygen and for nitrous oxide have been very simply arranged by tapping into the inlets as they pass through the base of the flowmeter and leading them in again at the head, the actual components used being four standard gas angle-pieces and two gas taps with some copper tubing. Provision for dismantling the flowmeter was made by the insertion of two double pipe unions designed for a motor-cycle petrol system.

The standard Boyle's ether bottle, or a Goldman drip, can of course be plugged in as required; and, owing to the use of standard rebreathing bag and tubing mounts, it may be placed either near the flowmeter or in the circuit. The original yoke for the cyclopropane cylinder was the carbon dioxide bracket off a Magill, but this has subsequently been replaced by a modern cyclopropane yoke of smaller dimensions.

It will be noted that, despite the limitation in flow, it was possible to obtain very simply a closed circuit adequate and satisfactory for the work in hand, and at a very small cost, thus overcoming the difficulties caused for us by technical delays both in the ordering and in the supply of standard apparatus. Great credit is due to the members of the works department for their co-operation in fixing up the machine—only the lack of equipment prevented their constructing a head with the conventional type of slide—and to the I should like to express my thanks.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 20 1946

THE COMMITTEE STAGE

The National Health Service Bill has now passed the Committee Stage. The proceedings of the Committee have been fully reported each week under Parliamentary Notes, and in the current Supplement we summarize at length the main points of the prolonged discussions that have taken place. It was not expected that any fundamental alterations would be made, and expectations have not been disappointed. The Government was defeated in what Mr. Bevan called a Pyrrhic victory when subsection 4 of Clause 42 was by a majority vote deleted. This subsection allowed an appeal to the Minister against any direction of the Tribunal. An amendment to provide for an appeal to the High Court was, however, defeated. Although no major change in the Bill was to be expected, the value of the Committee Stage is that a Bill is subjected to the closest scrutiny, line by line, and clause by clause. Mr. Bevan did not close his mind to a number of points that arose and exemplified his intention to keep flexible the structure he is erecting to house the new National Health Service. But on many points he remained adamant. The buying and selling of practices, for example, he persists in regarding as "an intrinsic evil"—a moral judgment which seems strangely out of context. A controversial issue is best met by the argument and not by *ex cathedra* statements. It may be noted that the Committee Stage was dealt with "in Committee upstairs" not "in Committee of the whole House," the latter being the course reserved for the more important Bills. The Bill with the alterations and amendments made in Committee now passes to the "Report Stage," when there will be some further debate. After this, the Third Reading, and the Bill will pass to the Lords.

The status of the Central Health Services Council is to be secured by making any variation in its constitution subject to a negative Resolution of Parliament. This means that a regulation is placed before the House and can be annulled by a Prayer. Regulations needing an affirmative Resolution are stated in the Bill. Such regulations were instanced by the Minister as dealing with superannuation and finance: "They have to be approved by the House before they come into operation." He pointed out that an Order was an administrative act and did not come before the House as either a negative or an affirmative Resolution. As an instance of the kind of matter that will be dealt with by Order, the Minister referred to the making of a regional authority as being a question not of principle but of "convenience, sound organization and administration." While he admitted that Ministers were taking many more powers to issue Regulations and Orders than previously, he suggested that the House of Commons also had more protection than before through the mechanism of the Statutory Rules and Orders Standing Committee. He observed, incidentally,

that almost the whole of the National Health Insurance Act was operated through the issue of Regulations. Mr. Bevan wants to see the Central Council not as a specialist body but as one "limited to giving general advice." The Central Council would have representatives on each of the Standing Committees, and these would be set up after consultation with it. The Committees were not named in the Bill, because he thought it best that they should be set up from time to time according to need. On the publication of the annual report of the Central Council he agreed to the insertion of the words "after consultation with the Central Council" in the sentence in subsection 4 of Clause 2 referring to the Minister's power to withhold the report or any part of the report "if the Minister is satisfied that it would be contrary to the public interest." He promised to make it clear, if it were necessary to do so, that a Standing Committee will have power of initiation. But the powers of initiation of the Central Council seem to be restricted. Referring to the subject on which the Central Council might advise, Mr. Bevan said: "Where it might be limited, and I think properly limited, is in connexion with Industrial Health Services." If the Central Health Services Council is to be an effective body composed of men of experience and with a sense of responsibility, such limitation would seem to have little logic in it.

Perhaps the most important aspect of the future hospital services is the number of regions into which the country is to be divided. This is closely linked with the desirability of bringing the regional organization into close contact with a university. Mr. Bevan intends at an early moment to appoint the Regional Boards and to ask them to prepare draft plans. This will be done by Order. But he has promised to "see if it is possible to frame some words by which the constitution of the regional areas can be dealt with, not by affirmative, but by negative Resolution." Mr. Willink had pressed that the constitution of the region should be dealt with by affirmative Resolution. The appointed day on which the Act will come into operation is April 1, 1948, but the Minister has the power to bring parts of the scheme into operation on different appointed days. It will, therefore, be possible to notify voluntary hospitals about their position under the Act before 1948: the Regional Boards will make their plans as soon as possible after the Act has been passed. The Minister intends that the Hospital Management Committee shall have power to hold endowments. He also promised to see if it was possible for Hospital Management Committees to receive gifts: "People normally do not give gifts to a Board; they give gifts to a hospital." When the functions of Boards and Management Committees come to be defined he intends there should be "considerable devolution of responsibility" to the latter. In answer to a question on private practice for specialists, Mr. Bevan said: "This is a field in which the utmost flexibility will have to prevail." So long as he played even a small part in the public service a specialist would be considered to be in it. But Mr. Bevan also stated that he wanted a specialist "to spend as much time in the hospital precincts as possible." As to the recognition of general practitioners as specialists, he observed that he would first seek the opinion on this of the Central Advisory Medical Committee, and, secondly, that he

consult the profession as to what body ought to advise on the definition of a specialist for the purposes of the National Health Service. Discussing "general practitioner hospitals," he observed that they should be available for the chronically ill person who could not be treated at home but could be looked after by a general practitioner in the case where specialist treatment was not required. But these hospitals would not be available to general practitioners who remained outside the service.

The long debate on Health Centres showed that there is still some confusion of thought about the exact place of these in the new health scheme, and also that Mr. Bevan is aware of the need for experiment as an important factor in their development: "It is obvious that we shall have some experimentation," he observed, but not with "the initial idea." A Health Centre serving too huge a population might be too far from some patients' homes, yet a fairly large unit was necessary if they were to be able to afford diagnostic apparatus in the Centres. While it must be a duty for local health authorities to provide Health Centres, the extent to which this could be imposed depended upon the extent to which facilities could be provided. It would be some time before the Health Centres were available. His view was that until they could build Health Centres "of a new and agreeable character" they would have to adapt old buildings. The Health Centre Service would evolve from year to year as experience dictated. Mr. Bevan considered that for the Regional Board to provide Health Centres would be administratively impossible. He struck a slightly unreal note when he said: "If we can get a stream of healthy people attending a Health Centre, it becomes a Health Centre; but if we merely have morbid people going to a Health Centre, it becomes a Morbid Centre." It does not seem to have occurred to the Minister that healthy people would not want to spend their time waiting to a building equipped with diagnostic apparatus. In fact, whatever fine words may be used, Health Centres will be multiple surgeries, at which, it is true, the sick, once healed, may well receive health instruction. He added the much needed assurance that "there will be complete privacy for any confidences they [the people] may repose in their doctor. . . . I agree that the medical history should go from one professional hand to another and that it should not be available for secular scrutiny." And another welcome intention was expressed when he said: "The Minister will not accept the odium of giving directives about any particular form of therapy." This statement was made in a discussion on Clause 12 relating to the functions of Boards and Management Committees, and may be presumed to extend to the general practitioner as well as to the specialist.

Mr. Bevan said that the method and amount of remuneration of the general practitioner should be dealt with by Regulation. He was firmly convinced that there should be "an element of basic salary in the doctors' remuneration." He admitted that he found it difficult to reconcile the free choice of doctors with the abolition of partnership between patient and doctor. He thought that he expressed any definite opinion he would prefer consultation with representatives of the profession

should reach a more advanced stage, and observed that in some circumstances it would be necessary to weight the basic salary in order to get sufficient doctors into the under-doctored areas. He had an entirely open mind on the desirability of "declining" (i.e., tapering) the capitation rate. He was prepared to look at this question again as it was not a matter of fundamental principle. On the question of assistance, he thought this a desirable way of introducing a doctor to general practice, but general practitioners could not have an unrestricted right to engage any number of assistants they liked as this would interfere with the proper distribution of doctors. Assistants would not be on the list of the Local Executive Council, but the provision of assistants to principals would be taken into account by the Executive Council and the Medical Practices Committee in deciding whether an area was sufficiently doctored. In the event of a vacancy, the Executive Council would notify the Local Medical Committee; the latter would then be able to suggest the name of a suitable doctor, and this recommendation would "have very great weight." If the Executive Council agreed, it would recommend the filling of the vacancy to the Medical Practices Committee. "In fact," Mr. Bevan said, "the individual doctor will be selected by the Local Executive and not by the Medical Practices Committee." On the question of partnership, Mr. Bevan stated: "Where a partner has not got a panel, if he is in partnership with doctors who have got a panel, I am advised that nothing in this Clause [35] inhibits that partner from selling his practice." If he thought that the language of the Clause might have the effect of dissolving partnerships, he would try to seek protection against it, but he was advised that the Clause had no such effect.

Until the Bill has become an Act it will not be possible to ascertain the fully considered views of the medical profession on the Government's main proposals for a National Health Service. We shall not attempt now to forecast what the reaction of the majority of doctors will be to the principal features of the Act, on the assumption that the Act will be the present Bill amended and altered in accordance with promises made in Committee. In the meanwhile, we may note that in Mr. Bevan's view a considerable time will elapse before the whole of the scheme is in operation. In his own words: "We are short of some of the requisites with which to man it—we are short of sufficient doctors, sufficient specialists in particular, sufficient dentists, and with regard to a very vital provision in the Bill, sufficient Health Centres."

WORLD HEALTH ORGANIZATION

A new international health organization is being shaped under the broad dome of the United Nations. It is passing through much the same stages as the original health organization of the former League. To those who recall the Cannes Conference, Article 23 of the League Covenant, the Assembly resolution of 1920, and the appearance of the International Health Organization as one of the three technical bodies of the League (the others being concerned with economics and finance and with communications and transit), the parallel is almost startling, and, as the League disappointed the high expectations formed of

it is somewhat ominous. Yet the Health Organization has been one of the few great successes in the international field during the last quarter of a century, and on its dissolution its inheritor pays it a tribute in words and an even more flattering tribute in copying its constitution and procedure.

At San Francisco a year ago the United Nations subscribed to a declaration calling for an international conference to establish a Health Organization. One of the articles of the San Francisco charter reads that the United Nations shall promote solutions of international health and related problems. A small preparatory committee of experts was set up in the early part of this year by the Economic and Social Council of the United Nations, and, with Dr. G. B. Chisholm, of the National Health and Welfare Ministry in Canada, as rapporteur, drew up a report which was sent to a drafting committee of delegates from 14 nations (including the United Kingdom, the United States, and Soviet Russia), under the chairmanship of Dr. Ramaswami Mudaliar, whose presidency of the recent Economic and Social Council meeting in New York has revealed him as one of the outstanding personalities on the international stage. The report proposes a world health organization as a specialized agency through which the States will co-operate for the protection and promotion of health in every country. Its aim will be to achieve the highest possible standard of physical and mental health for all peoples, to prevent the occurrence of disease and control its spread, to stimulate the development of improved health services, and to weld together for executive action the scientific and professional groups which contribute to health advancement. In emergencies it will render aid at the request of Governments. Its various functions are set out in the draft report in lettered paragraphs which almost exhaust the alphabet. They include the establishment and maintenance of an epidemiological and statistical service, the development of information services concerning health and medical care, the promotion of conventions and agreements with regard to international health, the setting up of standards for pharmaceutical, biological, and related products, and for diagnostic procedures so far as this is desirable. Other suggestions made to the Economic and Social Council when the report came under review were the undertaking of relief measures in war-scarred territories such as Greece, and particularly measures for the protection of children and the control of malaria and tuberculosis.

It is proposed that the membership of the organization should be open to all States. One question to be settled is whether trust territories, protectorates, and colonies, not eligible for separate membership of the United Nations but having their own health administrations, will be allowed to take separate action concerning parts of the work of the organization, such as international sanitary conventions. The work will be done through a world health conference to be held at least once a year, at which broad policy will be determined, activities reviewed, sanitary and quarantine regulations laid down, the international nomenclature of diseases and causes of death adjusted, and, if necessary, standards established for such things as the purity and potency of drugs. The executive of this

conference will be a body of from twelve to eighteen persons designated by the member States and will meet at least twice a year. There will be a director-general and the usual secretariat and commissions and committees. It is proposed that the staff should be under the same statutory regulations and have the same salary scales as the staff of the United Nations, and they will be expected to observe the same international loyalty and to have the same freedom from national influences. A matter undecided is whether the organization should be housed at the headquarters of the United Nations or should have an independent location. Some think that the latter would be preferable as signifying dissociation from political influences, and also as enabling the organization to be in close proximity with other specialized agencies, such as the Office International d'Hygiène Publique in Paris, the League of Red Cross Societies, and perhaps U.N.R.R.A., supposing its activities continue.

International movements are necessarily slow. They cannot proceed by the hammer rule of the majority but only by gradual adjustment and compromise. Resolutions, which seem to consist mostly of preamble, filter through a succession of assemblies and committees of diminishing size until they reach a drafting subcommittee, and then a report appears and makes the reverse journey. Even when a convention has been fashioned it has to await the ratification of Governments. But, as Dr. Johnson said of women's preaching, the surprising thing is to find it done at all. Moreover, during this circumlocutory procedure a certain amount of education is always going on; people are becoming accustomed to the idea of international co-operation in new fields, and gradually a capital of goodwill is accumulated. It is not without significance that after each of the two world wars those concerned with establishing the machinery of peace should have regarded health as one of the necessary conditions of such establishment. As one member of the Economic and Social Council put it, "The moral credit of the Health Organization's work should benefit the United Nations."

LOCAL COOLING

Recent work on the effects of local cooling has thrown light upon two contrasting problems: (1) the nature, prevention, and treatment of frostbite, and (2) the virtues of local refrigeration as a therapeutic measure. The Holme lectures¹ by the late Sir Thomas Lewis dealt with the reaction of the skin and subcutaneous tissues to cold and the damage resulting therefrom. Lewis emphasized that there are two distinct types of cold injury to the skin—namely, by direct action and by freezing. Although both processes have often been confused within the term "frostbite," Lewis would restrict that term to the latter type of injury. The three clinical conditions of chilblain, erythrocyanosis, and trench foot were looked upon by Lewis as different manifestations of the same process—namely, prolonged action of cold. Histologically there is much in common, the lesions being those of subacute or chronic inflammation. With regard to the treatment of frostbite, Lewis emphasized that there is no fundamental difference between the lesions due to freezing and those due to heat, and that the rational treatment of the lesions of frostbite

¹ *British Medical Journal*, 1941, 2, 795, 837, 869.

and of a scald have much in common. If the patient is seen at a time when the tissues are frozen then thawing must be done slowly to avoid undue swelling and pain. Friction is dangerous, as it may injure the friable tissues.

Later studies by R. Greene² have shown that cold produces a transudation of fluid into the surrounding tissues. The red cells left behind may silt up the blood vessels and occlude the circulation, but at all events true thrombosis does not occur primarily. This observation has been supported by the fluorescein studies of K. Lange, L. J. Boyd, and L. Loewe,³ who found that the aggregation of red cells within the vessels could be washed away by saline perfusions. Not until 72 hours after local freezing does actual thrombosis occur, to be followed by gangrene. Furthermore, there was some suggestive evidence that the intravenous use of heparin shortly after local freezing prevented the onset of gangrene. The authors are undertaking experiments to determine the simplest means of heparinization and the longest interval between exposure to cold and the onset of effective therapy. The usual treatment of frost-bitten limbs to-day takes the form of continuous local refrigeration. R. Greene,⁴ with the co-operation of Mr. R. J. Simpson, has devised a "therapeutic refrigerator" wherein CO₂ snow is packed upon a tray below which the patient's limb reposes. Earlier D. R. Webster, F. M. Woolhouse, and J. L. Johnston⁵ had advocated the use of dry refrigeration in the treatment of cases of immersion foot.

This practice of deliberate local cooling ties up with a good deal of recent work upon the beneficent effects of refrigeration. According to N. E. Freeman⁶ gangrene results from a discrepancy between the demands of the tissues and the supply of blood to meet these nutritional needs. F. M. Allen⁷⁻¹⁰ has shown that an animal's limb will tolerate a cutting off of its circulation for 15 hours at room temperature, but for 54 hours at zero. Small loops of bowel can be exposed to refrigeration for 16 hours and recover. Reducing the temperature of a ligated limb increases the local metabolism and the danger of both gangrene and shock. Local injections of strychnine can be tolerated in much greater amounts if the surrounding temperature is low. B. Brooks and G. W. Duncan¹¹ showed that warmth applied to an infected wound hastens necrotic and inflammatory processes, while cold reduces them. These experimental observations have important bearings upon the problem of the treatment of gangrenous extremities. "That damaged patients and damaged limbs have always been warmed is not in itself a sufficient proof of its efficacy." The experiences of "refrigeration anaesthesia" for amputations upon patients who are poor surgical risks^{12, 13} are encouraging and may be adduced as evidence in the controversy of "cold versus heat" in the correct treatment of ischaemic limbs.

It would however be unwise to accept finality at this stage. It is doubtful whether the case for cold therapy has been proved up to the hilt. The German and Russian clinical experiences during the war are not yet available to all. H. Binhold's paper in 1942¹⁴ entitled "Should Frostbite be Rewarmed Slowly or Rapidly?" has probably not yet received a sufficiently wide or critical audience. If cold environments are to be maintained the question arises as to how long this should be kept up, and what later

reactions, if any, are to be expected. Are necrotic or infective processes merely inhibited, to return with added virulence when room temperature is eventually attained. Brooks and Duncan's work suggested that after local cooling has been discontinued the morbid processes advance . . . "at the expected rate or greater," and the final necrotic area proved to be larger in cases treated earlier with cold applications.

A study of high altitude frostbite by L. Davis, J. Scarff, N. Rogers, and M. Dickinson¹⁵ deserves close reading. The writers compared a series of patients treated with continued cooling for 24 to 48 hours, with cases treated by exposing the damaged parts to room temperature. They concluded that the results obtained were equal to or better than those obtained by continued cooling though there might have been more blistering in those exposed to room temperature, there were less pain and eventually less tissue-loss. Blocking of the sympathetic trunk and of the stellate ganglion failed to augment the circulation in damaged extremities where the capillary walls had been injured or where thrombosis had occurred at the arteriolar-capillary junctions.

PLEURAL SHOCK OR CEREBRAL AIR EMBOLISM

Pleural shock is one of those conditions which have been handed down uncritically from book to book. Most people have heard of it and some believe in its existence, but few can quote an instance from their own experience. The first account of the condition appears to be that of Roger who in 1864 described it as an eclamptic fit with cardiac respiratory embarrassment, tonic and clonic muscular contractions, loss of consciousness, and sometimes death. Most subsequent accounts give a similar description. Andosca and Foley¹⁶ point out that this syndrome agrees in all particulars with that seen in cases of cerebral air embolism. There is plenty of clinical and experimental evidence to show that air embolism arises as a complication of pleural puncture, and these authors conclude that so-called pleural shock is due to air embolism and not to a pleural reflex. They quote a number of examples to support this conclusion, and also an instance of novocain poisoning in a sensitive subject giving rise to a similar symptom complex. This is a further argument against the use of local analgesia for straightforward pneumothorax refills, a subject which has recently provoked much discussion in the correspondence columns of the *Journal*.

Fortunately, cerebral air embolism is uncommon. Andosca and Foley record 12 cases, of which only one proved fatal, in a series of over 90,000 pleural punctures. It has been shown experimentally that a very large volume of air has to be introduced into a systemic vein to produce a fatal result—a sad blow to some writers of detective fiction—but a very small amount of air injected into a pulmonary vessel causes immediate death. There is no doubt that careful handling of the exploring, or refilling, needle, so that the lung is not punctured, will help to prevent this complication. When an air embolism occurs, little can be done to limit its effect, but if the patient survives the first few minutes he will probably recover completely. Lowering the head has been advocated, but the experimental work of Van Allen, Hridna and Clark¹⁷ suggests that this may cause the air to enter the coronary vessels instead of the cerebral, with equally fatal results. These authors advise the administration of oxygen under pressure, but it will rarely be possible to do this in time to save life.

CLINICAL PATHOLOGY IN THE HOSPITAL SURVEYS

BY

S. C. DYKE, M.D., F.R.C.P.

The recognition given to clinical pathology as an essential part of the national hospital service is a striking feature of the survey of the hospital service of England and Wales lately made for the Ministry of Health. The reports so far published are unanimous in regarding an efficient service in clinical pathology as essential for the proper practice of medicine, no matter where carried out; further, they agree in taking it for granted this service must be organized in close integration with the hospital service and its practice carried out in laboratories attached to hospitals. The surveyors of all areas in this respect speak with one voice, but individually they have concentrated their attention upon varying aspects of the subject.

Hospital Pathology; Pathology and General Practice; Pathologist as Consultant

Speaking in particular of the hospital service, the surveyors of the West Midlands area lay it down that "the pathological service must be efficient if the work of any clinical department of a hospital is to be of adequate standard. . . . All general hospitals should be provided with a pathological department within the buildings which would do the day-to-day routine investigations."

Other area surveyors have laid particular stress upon the need felt by the general practitioner for facilities for pathological service. The surveyors for the Sheffield and East Midlands area state: "In conversation with general practitioners we have heard repeatedly of certain facilities that they feel should be available to them through the out-patient service of the hospitals. Most general practitioners would like to have the right to send specimens, or patients from whom the specimens could be collected, to the hospital for pathological investigations. . . . On balance we believe that there is good reason to permit certain work of this kind." The same view is even more forcibly expressed by the surveyors for South Wales and Monmouthshire: "It is also desirable that patients referred by practitioners to consultative centres for such specialist opinions as the pathologist and the radiologist can give should have access to them without the barrier commonly interposed of having first of all to see a physician, surgeon, or other specialist."

They proceed: "But such consultations should take place at a common centre where the consultant, whether he be physician, surgeon, pathologist, radiologist, or other specialist, can avail himself of the service of any colleague whose service he may value." The surveyors for London and the surrounding area also lay stress upon the importance of consultation between practitioner and pathologist: "One of the criticisms most frequently made was of the arrangements—or lack of arrangements—for pathological services. . . . There was little opportunity for the personal consultation between the pathologist and the practitioner which is an essential feature of clinical pathology." The role of the pathologist as consultant is also emphasized in the survey of the Yorkshire area: "It is desirable that . . . there should be a closer contact and consultation between the practitioner and pathologist. . . . In general the pathologist should be considered as a consultant differing in no way from a consulting physician or surgeon."

Grading of Laboratories

All the surveys agree that clinical pathological laboratories must be attached to hospitals and that they must differ in size and importance according to the amount and the degree of specialization of the work undertaken in them; smaller laboratories should depend upon those larger and more fully equipped and staffed. Thus the West Midlands survey suggests that "in larger hospitals . . . it is necessary to make provision for special investigations. Hospitals which have these larger laboratories would be able to do work for those less fully equipped."

The North-western surveyors, having discussed the grouping of hospitals, indicate that "the hospital districts recommended in this report are suitable for laboratory districts, each to have a laboratory in whatever hospital is most suitable. . . . Other

hospitals would have a subsidiary laboratory or 'side room,' according to their beds."

The Sheffield and East Midlands survey expresses the same view: "Laboratory workers even more than many other specialists should be associated with major centres. There should be a medical pathologist working in all but the smallest hospital centres and several in the largest hospital centres. There should be an Institute of Pathology in each large centre, with a team of pathologists and biochemists responsible for the ordinary clinical pathology work. . . . The clinical pathology work in the smaller centres will be done by a medical pathologist of junior standing, who should be attached to the Institute of Pathology of the appropriate larger centre and who should be supervised and periodically visited by the head of the Institute."

Three grades of hospital laboratories are envisaged in the survey of the Bucks, Berks, and Oxfordshire area:

1. Regional. This should be the central laboratory of the region, capable of dealing with any examinations in hospital pathology, with staff sufficient to act in a consultative capacity to other laboratories in the region. If possible it should be at the university centre.
2. Divisional laboratories capable of dealing with all examinations apart from those of a specialist nature.
3. Smaller laboratories situated in smaller hospitals, capable of dealing with simple hospital pathological investigations only and looking to the divisional laboratories for considerable help both in the wards and in the laboratory.

Role of the Medical Schools

The Sheffield and East Midlands survey draws particular attention to the mutual benefit to be derived from close association between the pathological departments of the divisional hospitals and that of the medical school of the region: "It is most important that the medical teaching schools should be closely associated with all this pathological work. . . . In this way the academic pathologist is constantly in touch with the clinical pathologist's problems, and the clinical pathologist is in contact with the research work proceeding in the university department."

One particular aspect of this mutual benefit receives attention in the Yorkshire survey, which points out that much valuable post-mortem material, now lost to the university departments, would, under such an arrangement, become available to them: "There is a great waste of material available for pathological investigation and research. This is particularly noticeable in the performance of post-mortem examinations, and is the more deplorable in that post-mortem examinations and the checking and correlation of clinical symptoms and diagnosis with the post-mortem findings are the foundation of clinical and scientific knowledge."

Administrative Organization; Public Health Pathology

It is implicit in the recommendations of all the surveys that the regional laboratory service should be closely integrated with the Department of Pathology of the regional university, but it is not implied that the divisional laboratories of the region should come under the control or direction of this department. The North-western survey recommends that the divisional laboratories of the hospital districts of any given region "should all be under the control of a chief pathologist of the district, who would be a member of the laboratory staff of the administrative area" and would be designated Director of Laboratory Services and exercise some degree of supervision over the service of the whole area. . . . The main laboratory of each district would be definitely associated with the university."

All the surveys, by implication if not by direct expression, agree in regarding clinical pathology as constituting a sphere of work apart from, though by no means independent of, public health pathology. The Sheffield and East Midlands survey is specific: "The public health bacteriology for the area is not to be regarded as a subordinate part of the hospital pathology service, and it will probably be organized on parallel but independent lines working in touch with the preventive medicine departments of the authorities of the area. Nevertheless, it is important that there should be close contact between the two groups, and it is desirable that, where possible, they should work in the same building so as to preserve the closest possible liaison."

The New Approach to Medicine

The large amount of attention devoted by the surveyors for England and Wales to the service in clinical pathology, and the unquestioned acceptance of the view that the practice of clinical medicine either in or outside of hospital is impossible without adequate laboratory assistance, are an expression of the revolution in the approach to medicine which has been gathering strength in this country for the past quarter of a century. Of particular significance is the general agreement that satisfactory results cannot be attained by mere isolated examination and report on specimens, but only by direct consultation between practitioner and pathologist.

Scotland—a Contrast

In contrast to the importance attached to clinical pathology by the surveyors for England and Wales is the paucity of reference to this service in the Scottish surveys. These number five: in two no reference is made to pathology; in the remaining three the surveyors make no reference to the desirability of bringing practitioner and pathologist into consultation, but content themselves with commending the development of a pathological service involving only the transmission of specimens for examination and report to certain designated centres. This striking contrast seems to indicate some fundamental difference between the approach to medicine in England and Wales as opposed to Scotland.

RELIEF OF FAMINE

A medical conference on famine relief was called by the Health Division of UNRRA at its European Regional Office on May 25. Those present included: Dr. C. N. Leach, Prof. H. P. Himsworth, Dr. M. Pyke, Dr. Janet Vaughan, Dr. Harriette Chick, Miss Margaret Hume, Dr. J. F. Loutit, Dr. I. A. Anderson, Dr. D. A. Smith; for UNRRA: Dr. N. M. Goodman (Director of Health, European Regional Office), Dr. J. Cottrell, Dr. A. P. Meikicjohn, Dr. H. S. Collins, Dr. B. H. Smith, Miss Jean Ritchie. The following is a summary of the principal recommendations.

Treatment of Starving Patients

The treatment of starving patients requires an adequate supply of spray-dried skimmed-milk powder, dried eggs, pre-cooked cereals, glucose (preferably fortified with vitamins), fats, fruit juices, and flavouring agents. Apart from the lack of calories, shortage of protein is likely to be the most serious consideration, and therefore every effort should be made to increase supplies of protein-rich products, such as prepared yeast, soya, dried liver powder, protein hydrolysate for oral use, and dried slaughter-house plasma. Such products would be a very useful supplement to the diet of the starving and, in an emergency, could be used in partial substitution for dried milk and eggs. In order to hasten recovery, to prevent relapses, and to avoid overcrowding the hospitals, starving patients should be treated with a diet sufficient to supply at least 3,000 calories daily. Hospitals dealing with severe cases of starvation should have supplies of dried plasma available for intravenous therapy, in normal or double concentration as indicated.

It is not thought likely that there will be any serious incidence of florid vitamin deficiency diseases (this statement is not intended to apply to maize-eating communities). The conference considered that supplies of vitamins should be for oral use only and in amounts suitable for prophylaxis rather than for treatment. The greater part of vitamin requirements would best be met by the provision of natural, rather than synthetic, sources of vitamins—e.g., yeast extract, liver extract, fish-liver oils, and fruit juices. Tables, giving the amounts of special supplies needed to treat 100 starving patients, were prepared and agreed.

If the supply of milk for children should fail, rickets and vitamin A deficiency would become serious problems. Stocks of cod-liver oil should be on hand against such an eventuality. Because the administration of a single large dose of vitamin D has great therapeutic advantages in the prevention of rickets, adequate supplies of concentrated vitamin D in oil would be useful. Sulphonamides would be needed for the treatment of

diarrhoea and the intercurrent infections, which are particularly liable to attack starving people. Penicillin would also be needed.

Present Supplies

Supplies of milk in post-war Europe have been sufficient to provide for the essential needs of young children; but there have been very little milk for adults and the older children. This combined with the high phytic acid content of the long-extraction bread grains at present in use throughout Europe, makes the diets of adults and older children particularly deficient in available calcium. It is therefore recommended that calcium carbonate should be added to the bread. The general diet is also deficient in available iron, and in many parts of Europe anaemia is apparently prevalent. It is therefore recommended that efforts should be made to provide additional iron, in medicinal doses, especially for pregnant women and women employed in factories. Facilities for communal feeding in factories, schools, and elsewhere should be utilized to the utmost even if the factories and schools are closed.

Rationing systems in Europe have succeeded in providing fairly adequate rations for young children; but older children who should be growing rapidly, have often subsisted for long periods on diets providing insufficient calories for their needs. For this reason, older children and adolescents may require special consideration in the event of famine. It is obviously desirable to make the utmost effort to maintain adequate food supplies for children of all ages, but, if a fall in the calorific value of the official ration to very low levels becomes inevitable, priority over children may have to be given to the workers in essential community services, in order to prevent a complete breakdown of civilized life. In the same way, it may become contrary to the public interest to give extra food to hopeless invalids and chronic mental patients. In order to lessen the effect of shortage of calories, every effort should be made to ensure sufficient heating in living and working quarters during the winter. In urban areas, evacuation of non-essential population, children and non-working adults, to rural areas and even to other countries, should be promoted and encouraged.

Famine in a European city might be expected to affect first those living alone, the elderly, the occupants of institutions and those without regular employment. It would be important to provide "flying squads" to search out such cases. Provision should also be made for special and regular medical inspection of orphanages, convents, old people's homes, mental hospitals and gaols. Thereafter, ambulant cases of hunger oedema would begin to appear in increasing numbers, and would require supervision and special treatment at clinics. A considerable increase in out-patient clinic facilities would be needed, including "ambulatoria" attached to soup kitchens and other places where people congregate. Large numbers of hospital cases need not be expected at the outset, although later it might become necessary to provide extra hospital space. Doctors, nurses, health visitors and others would be needed to staff "flying squads," "ambulatoria," and inspecting teams for institutions. Consideration would have to be given to the best way of recruiting and equipping this emergency staff from the local population. UNRRA, military, and voluntary relief organizations.

BRITISH-SWISS MEDICAL CONFERENCE

Arrangements for the British-Swiss Medical Conference, which is to be held in Basle from Sept. 16-21, are proceeding, and the following have accepted the invitation to speak: *British speakers:* Sir Hugh Cairns, Neurosurgery; Dr. E.
